ousers. Shoes much about the same price as in
and, but not so good."

xtract of a letter from a farmer, who left the parish
Fergus in the summer of 1834, and settled in
ownship of Whitby, Upper Canada:—"With the
e of Mr D—— and Mr S——, I bought my
ut farm, which I shall now give you some ac-
t of. I have ninety acres of good land, seventy
hich are cleared; and on thirty acres of this
never was any crop, and but few stumps to clear
perhaps not above thirty on each acre. About
ty acres are altogether free of them, and I think
I have the whole cleared this season. I have a
orchard, containing about 140 trees, one-half of
h are in full bearing, and the other half planted
year. The barn is good, but the dwelling-house
r indifferent. There are three log-houses on the
, two of which let at L.6 each per annum. I have
ht a pair of oxen, which cost me 70 dollars, and
cows, one of which cost L.3, 10s., and the other
10s. currency. The cattle here are very good: I
r expected that I should see such in America.
horses are excellent, and although of the blood
, can endure a great deal of fatigue. I had almost
otten to tell you the price of my farm. It cost me
0 sterling. You may think this a very high price,
ou cannot get woodland here under 8 dollars an
, and it costs 12 dollars to clear and fence it. If a
can buy a cleared farm at L.5 per acre, or L.5, 10s.,

he is much better, if he has the money, than to go into the woods. I have ten acres of summer fallow ready to sow down with wheat; four acres of potato land; four acres where there was Indian corn, which I think I shall have ready to sow down in the course of ten days. I will sow the rest with spring crop, say oats and peas. I fear nothing in this country save the heat in summer; but I have been told, if I stand out this summer, I need not be afraid, as the oldest man in the place does not recollect such a warm season. We are at the same distance from church as we were at Cairnhill, and have two schools within two hundred yards of the door. A blacksmith and wright, a saw-mill and brick-work, are all about the same distance. A person here can have every thing as in the old country, if he has money. Wheat is very cheap. The best does not bring more than 3s. 6d. per bushel; but it is expected to rise very soon. The crop of it was excellent this year, as was also the Indian corn. If any of my old neighbours think of coming here, they need not fear of getting a farm, as there are always plenty to sell."

Extract of a letter from a millwright who left Turriff in the spring of 1834, to a gentleman there:—"The steam-boat fare from Quebec to Montreal was 6s. currency. I sailed from thence to Bytown in a barge—fare 7s. 6d. currency; and 2s. currency for each cwt. of luggage. From Bytown I went by a steamer to Kingston, which cost me 5s., and for each cwt. of luggage 9d.; from Kingston to Toronto, by a similar conveyance, 7s. 6d., without any additional charge for luggage; and then from Toronto to Hamilton, which cost 5s. more. I found employment at none of these places; but did so at the town of Oakville, where a steam-boat was building. Wages, 37s. 6d. per week, for nine weeks. Boarding during this period, 10s. per week. I have now steady employment here, and get 26 dollars per month, with bed, board, and washing. Washing is very high—3s. per dozen of articles of apparel, supposing they were all handkerchiefs. Scotsmen are here more respected and feared than emigrants from other countries. When I commenced first, I had only one sovereign; but I have now L.16, and have besides bought a good many tools. I do not repent of coming here; but I should like to see my native place again, although I never would stop in it altogether. I would not advise any one to come to this country who is not possessed of firmness and persevering habits, as to a stranger every thing appears awkward and forbidding at first; but, if he is possessed of these qualities, he will eventually be sure of success."

CONCLUSION.

Very little remains now to be said regarding these colonies. In our opinion, the question of emigration is one of a very simple nature, and may easily be solved by every thinking person. We have proved beyond the possibility of doubt, that British America is a country placed in infinitely better circumstances at the present moment, than any part of Great Britain and Ireland. We have shown that, in most places, the climate is delightful, and the lands fertile. It is not denied that in many portions of the colonies agues and other local diseases prevail; but it admits of demonstration, that on the whole, they are as healthy as these islands. If the inhabitants of the low uncleared lands in North America be liable to agues and fevers, those of this country are, on the other hand, continually liable to colds and consumptions to a degree fully as dangerous; indeed, the *colds* of the island of Great Britain seem to rank as the most destructive of the diseases which affect mankind. Besides, every year, the continent of America, as it becomes cleared, is becoming more salubrious, and it certainly possesses extensive tracts of land already fully as healthy and pleasant as any part of England. If it be established that British America is that fertile and promising territory which it is represented to be, the whole of the question of emigration resolves itself *into this: are men who* are in difficulties in this country *willing to undergo the trouble* of removing thither, and of exerting themselves for a few years af arrive! As for the notion which obtains as to t of parting with early friends, and the place of ou that we take to be entirely fallacious. It is t of every man to go where his mental and physi perties can be most advantageously exercised. fundamental law of human nature, that mankin disperse themselves over the whole earth, to s the best means of subsistence and the most ag spot for their residence. Had intending emig proceed to a land of barbarians, where neither nor divine laws were understood or acted up where they had to settle on sterile deserts or wildernesses, we might excuse their hesitation to from their native country; but the case is quit rent. To emigrate to Canada, or any other colony, is simply to remove, as it were, to anoth of Great Britain. Distance is nothing; for moval of a family from the north of Scotland south of England would be attended with nea same trouble and expense; and, in each case, the would find itself surrounded with neighbours strange. But to emigrate to Upper Canada w means of purchasing a tract of land, holds out better prospect than to remove from one part o Britain to another. In this country, it now r a very great mental and physical effort to o comfortable subsistence. Nearly the whole of th and manufactures in the United Kingdom are into the hands of capitalists. The rich are be very rich, and the poor are sinking deeper and into poverty and wretchedness. The small farm tradesmen of England, Scotland, and Ireland, s placed in that peculiar condition, when emigr a country less occupied and overdone than the is almost imperative; for, looking around on al they see little chance of rising into better circum or of rearing their families in that comforta reputable manner which their feelings dicta such, therefore, British America offers a fair f removal and settlement. In these countries, la be had in full possession, at an expense of from to twenty times less than what is paid here by annual rent; and it is seen that in a space of fro to five years, the whole cost may be realised amount of the produce. In these colonies, mo there are no taxes; at least they are so very tr a penny an acre, we believe, for cultivated lan they are not worthy of being classed as taxes. are also no poor-rates, and no tithes, both of wh posts are severely felt in England. The emigr likewise have nothing to annoy him in a politica for in Canada he continues to be a British subj can claim all the prerogatives of such a distinct

In short, it appears to us that, excepting th backs attending the *first difficulties*, there is no s tial obstacle to a very considerable improve circumstances. But we entreat all who have a fidence in our advice, not to imagine that these ties will be trifling. They will be, on the contr very serious nature. Let all remember, that t see a country consisting of extensive dreary for terspersed with settlements on the rudest sca the roads are generally in a very bad conditio the cold of winter far exceeds what is general rienced in Britain; that many of the conveni civilised life can with great difficulty be obtaine above all, that every one *must work hard with hands*. We tell all, most distinctly, that thes will be seen and experienced; and that a gr will in all likelihood be suffered for some years ing, however, by patience and enterprise, got e early difficulties, the settler will unquestionably a competence, along with the blessing of men quillity, and be relieved of all fears respecting t ing of his family in a state of decent independe

sloped. For thousands of years this magnificent
an river rolled its placid and undisturbed waters
widely spreading forests, rich green prairies,

son who had in view an object of gain in every thing he engaged in. He talked much in praise of the rich interior country, and how rapidly it would be settled and cultivated, if possessed by the Americans."

PRINCE EDWARD ISLAND.

This rich and productive island is situated in the Gulf of St Lawrence, betwixt Cape Breton on the east and New Brunswick on the west, and is separated from Nova Scotia on the south, by a strait of about nine miles in breadth. It measures 140 miles in length, and is 34 at its greatest breadth. The general appearance of this island from the sea is level, but, on landing, the scenery is varied with gentle undulations. It abounds with streams and lakes, and in many places it is indented with bays, no part being more than eight miles from the sea. The soil is in general fertile, yielding good crops of wheat and other grains; and parsnips, turnips, carrots, potatoes, and almost all the common culinary vegetables, succeed well. This island has been recommended to such emigrants as possess a knowledge of agriculture with that of the curing of fish. The climate of Prince Edward Island is in some respects similar to that of the neighbouring countries. The winter is said to be shorter than in Lower Canada, and the atmosphere is noted for being free of fogs. Agricultural operations commence about the beginning of May, and the harvest is generally over by the end of October. The chief disadvantage this colony labours under, and which is equally applicable to the others near it, is the great length of the winter, which obliges the farmer to lay up a very large stock of hay for supporting his live-stock. The sudden manner, also, in which spring comes on, abridges the period for sowing and planting, thus leaving the agriculturist comparatively idle at one season, and obliging him to work severely at another. The inhabitants are chiefly from Great Britain and Ireland, with a few Dutch and Germans. Mr Macgregor characterises them as hospitable, kind, obliging, and as, generally speaking, a moral people. The island is governed by a lieutenant-governor, council, and house of assembly consisting of eighteen members, who are elected by the people. Charlotte Town, the capital, is situated on the north bank of the River Hillsborough, on the east side of the island. The town stands on ground which rises in gentle heights from the banks of the river, and its harbour is considered one of the best in the Gulf of St Lawrence. A small group of islands called the Magdalens, have been recently annexed to Prince Edward Island, chiefly as fishing establishments.

PERSONS WHO OUGHT TO EMIGRATE.

"The persons who may be inclined to emigrate to Upper Canada," says Howison, "are of three different descriptions, namely, the poor peasant or day-labourer; the man of small income and increasing family; the man possessing some capital, and wishing to employ it to advantage. Persons of the first class never would repent if they emigrated to Upper Canada, for they could hardly fail to improve their circumstances and condition. The poorest individual, if he acts prudently and is industrious, and has a common share of good fortune, will be able to acquire an independence in the space of four or five years. He will then have plenty to eat and drink, a warm house to reside in, and no taxes to pay; and this state of things surely forms a delightful contrast with those hardships and privations which are at present the lot of the labouring population of Great Britain.

It is evident that some descriptions of emigrants will succeed better in Upper Canada than others. Those who have been accustomed to a country life and to country labour, are of course more fitted to cultivate land, and endure the hardships at first attendant upon a residence in the woods, than artisans or manufacturers, whose constitutions and habits of life are somewhat unfavourable to the successful pursuit of agriculture. But every individual, who to youth and health joins perseverance and industry, will eventually prosper. Mechanics cannot fail to do well in Upper Canada; for when not employed in clearing lands, they will find it easy to gain a little money by working at their professions; and they likewise have the advantage of being able to improve their dwelling-houses, and repair their farming utensils, at no expense. Weavers, being ignorant of country affairs, and unaccustomed to bodily exertion, make but indifferent settlers at first, and their trade is of no use to them whatever in the woods. Married persons are always more comfortable, and succeed sooner, in Canada, than single men; for a wife and family, so far from being a burden there, always prove sources of wealth. The wife of a new settler has many domestic duties to perform; and children, if at all grown up, are useful in various ways."

Every candid traveller in Canada concurs in these views; and it may be observed, that they are equally applicable to the other districts noticed in this sheet. "Of this, I think," says Fergusson, "there can be no doubt, that either the moderate capitalist, or the frugal, sober, and industrious labourer or artisan, cannot fail of success. *Fortunes* will not be rapidly or even readily acquired; but it must be the settler's own fault if he does not enjoy, in large abundance, every solid comfort and enjoyment of life, and rear around his table even a *forest* of 'olive plants,' without one anxious thought regarding their future destination or provision."

PASSAGE.

There are two ways of proceeding to Canada—by the St Lawrence, Quebec, and Montreal; and by New York and the Erie Canal. The passage by the St Lawrence is tedious and troublesome, and we recommend all who can conveniently do so, to take shipping direct to New York; from that city they will at once go on by a steam-boat on the Hudson River to Albany, and from Albany be conveyed in a track-boat on the Erie Canal to Lake Erie, where they will find steamboats ready to convey them in all directions. For those who prefer the passage by Quebec, the following information is given by an official pamphlet:—"Passages to Quebec may either be engaged inclusive of provisions, or exclusive of provisions, in which case the shipowner finds nothing but water, fuel, and bedplaces, without bedding. Children under fourteen years of age are charged one-half, and under seven years of age one-third, of the full price; and for children under twelve months old no charge is made. Upon these conditions the price of passage from London, or from places on the east coast of Great Britain, has generally been L.6, with provisions, or L.3 without. From Liverpool, Greenock, and the principal ports of Ireland, as the chances of delay are fewer, the charge is somewhat lower [we would here strongly advise emigrants to sail, if possible, from a port on the west coast, as being a great saving of time, trouble, and expense]; this year the charge will probably be from L.2 to L.2, 10s. without provisions, or from L.4 to L.5 including provisions. [Emigrants intending to settle in New Brunswick, Cape Breton, or Prince Edward Island, will generally obtain a passage in the vessels bound for Canada; and ships for Halifax or Pictou in Nova Scotia are constantly sailing from the British ports.] In ships sailing from Scotland or Ireland, it has mostly been the custom for passengers to find their own provisions; but this practice has not been so general in London, and some shipowners, sensible of the dangerous mistakes which may be made in this matter through ignorance, are very averse to receive passengers who will not agree to be victualled by the ship. Those who do resolve to supply their own provisions, should at least be careful not to lay in an insufficient stock; fifty days is the shortest period for which it is safe to provide, and, from London, the passage is sometimes prolonged to seventy-five days." Having wound up his affairs in this country, and otherwise prepared himself and family for proceeding to the land of their adoption, it is recommended that the emigrant

h and rhubarb pills; 6 lbs. of epsom salts, and
f senna—these medicines are very dear here; tin
to fit the stove of the ship, and it is convenient to
e one for hooking on the rim of the grate when the
of the fire is occupied; kettle for making coffee,
Use no crockery, but instead, jugs and bowls of
brush pot, frying-pan, and tin kettle."

he best months for leaving England are certainly
ch and April. The names of the vessels to sail
generally advertised in the newspapers. The con-
ance of passengers to the British possessions in
th America is regulated by an act of Parliament
Geo. IV. cap. 21), of which the following are the
cipal provisions:—Ships are not allowed to carry
engers to these colonies unless they be of the height
ive feet and a half between decks, and they must
carry more than three passengers for every four
of the registered burden; there must be on board
east fifty gallons of pure water, and fifty pounds of
ad, biscuit, oatmeal, or bread-stuff, for each pas-
ger. Masters of vessels who land passengers, unless
their own consent, at a place different from that
inally agreed upon, are subject to a penalty of L.20,
overable by summary process before two justices of
peace in any of the North American colonies. The
rcement of this law rests chiefly with the officers
her Majesty's customs; and persons having com-
nts to make of its infraction, should address them-
es to the nearest customhouse.

f the emigrant prefers taking a passage to New York,
should make particular inquiry respecting the vessel
e to sail in, as the above law does not apply to ships
rying passengers to the United States. We know of
oung man with a small capital, who sailed from a
t in the east coast of Scotland for New York, in a
sel which was afterwards discovered to be not sea-
thy. After beating about for three or four weeks
he Atlantic, the vessel was driven through the Irish
nnel, and had to put into the Cove of Cork to
ergo repairs. The passengers were obliged to work
watches at the pumps, and six weeks were expended
ore the vessel really proceeded on her voyage, be-
s having to purchase a new stock of provisions. To
id a similar disaster, we would advise the intending
grant to inquire into the character of the vessel at
office of the company with whom she is insured, and
making any agreement with the captain, to be par-
lar in having it in writing. He should stipulate for
use of all conveniences in the ship; and also not to
obliged to land for at least twenty-four hours after
ting into port.

LANDING.

Previous to disembarkation, arrange your baggage
small compass, the fewer packages the better, but
e them well secured—old dirty clothing, large boxes,
other useless articles, are not worth the carriage.
ou have any provisions left, such as oatmeal, pota-
s, &c., you can sell them at Quebec at a profit, and
id the expense of transport, and you can purchase
ers' bread, butter, tea, sugar, and other necessaries
re suited for your journey. All sorts of provisions
y be bought cheaper, and generally of a better qua-
, in Montreal and Upper Canada, than at Quebec.
ss yourself in light clean clothing. Females fre-
ntly bring on sickness by being too warmly clothed.
your hair short, and wash daily and thoroughly.
oid drinking ardent spirits of any kind, and, when
ted, do not drink cold water. Eat moderately of
ery food. Avoid night dews. By attending to the
ceding directions, sickness will be prevented, with
er serious inconveniences. When every thing is
dy for disembarkation, and if the ship is lying at
hor in the river, take care in passing from the ship
the boat; avoid all haste, and see that your baggage
n the same conveyance with yourself, or left under
charge of some friend, with your name on it. If
ship hauls to the wharf to disembark, do not be in
urry, but await the proper time of tide, when th

ship's deck will be on a line with the quay or wharf. Passengers are entitled by law to the privilege of remaining on board ship forty-eight hours after arrival; and it is unlawful for the captain to deprive his passengers of any of their usual accommodations for cooking or otherwise; you may therefore avoid the expense of lodgings, and make all your arrangements for prosecuting your journey. If, previous to disembarkation, sickness should overtake you, proceed immediately, or be removed, to the Emigrant Hospital, in St John's Suburbs, where you will be taken care of, and provided with every thing needful until restored to health. Medicine and medical advice can also be had at the Dispensary attached to the Quebec Charitable Emigrant Society. This society will grant relief to all destitute emigrants. In Montreal there is a similar institution for the relief of emigrants. It is particularly recommended to emigrants not to loiter their valuable time at the port of landing, but to proceed to obtain settlement or employment. Many emigrants will find employment in the city of Quebec and its vicinity, as also in and about Montreal. Single men, in particular, are advised to embrace offers of this kind; but emigrants with large families had better proceed without delay to Upper Canada, as hereafter directed, or to situations in Lower Canada, particularly the eastern townships; and if they have sons and daughters grown up, they will find a sure demand for their services. Artificers and mechanics of all denominations, and farming labourers, if sober and industrious, may be sure of doing well. Blacksmiths, particularly those acquainted with steam-engine work, also good millwrights and sawyers by machinery, are much wanted in the Canadas. The current rate of wages lately paid to carpenters, masons, and other artificers, was from 3s. 6d. to 6s. or 7s. per day, according to circumstances; farm-labourers were paid at a lower rate. There is no demand for persons skilled in any of the ornamental professions, or for the preparation of articles such as are usually imported from England. A great number of labourers are usually employed on board ships, and about timber-yards, at Quebec and Montreal, who get from 3s. to 4s. 6d. a-day, and board generally found. The extravagant habits engendered in such occupations render it decidedly preferable for the labouring emigrant to proceed immediately to the country. Emigrants with families, and who are possessed of from £20 to £25, are advised to push immediately into the woods, in the vicinity of old settlements, where they can obtain provisions for their spare labour. The most vexing circumstance connected with money matters, is that the currency of the whole of British America is different from that which prevails in the United kingdom; in other words, a sovereign in England is different from a sterling in Canada. The money of Canada is locally of higher nominal value than what we understand by the term *sterling*, and is called Halifax currency. The difference varies; but it may be stated in general terms, that an English sovereign is reckoned to be worth 24s. or 25s. 6d. currency; or an English shilling is equal to about 1s. 2½d. or 1s. 3d. currency. If you take English money to Canada, you will receive these high prices for it; but if you wish to turn currency into sterling, for the purpose of remitting home, you will get a corresponding loss. All wages are, of course, reckoned in currency; therefore, when it is said you will receive 5s. a day of wages, the actual value of this in sterling will be somewhat less. The distinction between currency and sterling will be learned, of course, the moment you come to purchase or receive payment of wages in the former. We have heard very serious complaints on this point. From all we can learn, it is the interest of every employer to pay his workmen by an order for goods at a store, rather than to give the amount in cash; and it is the usage in the large places at which emigrants call, that such orders are given, it should seem, to get rid of a scarcity, does actually get more *goods than he would buy for* 1s. 6d. *in ready money*. This *an apparently high wage dwindles down to a trifle*,

Perhaps such practices are not resorted to by respectable employers, or may only prevail in parts of the country where a circulating medium is scarce; but we have considered it proper to mention the circumstance, in order to put emigrants on their guard. Always ascertain whether you are to be paid in cash or in goods, and act accordingly.

Having arranged all your business at Quebec, you will proceed without loss of time to Montreal, by steam-boat, on your route to Upper Canada. Two steam-boats ply (or lately plied) to Montreal, 180 miles up the St Lawrence, which is performed in from 24 to 30 hours. Take care not to engage a passage in any vessel from which you and your family will be obliged occasionally to come out and walk; we have heard of disgraceful instances of this kind of cruelty. The fares on board the steam-boats were lately as follow (but all may now be a little altered):—Deck passengers, adults, 7s. 6d. each; children under twelve years of age, half-price; and under seven, one-third. The routes and fares to the principal places were lately as follow:—

Quebec to Montreal, by steam-boats, - -	7s. 6d.
Montreal to Prescot, by Durham boats, -	6s. 3d.
Prescot to Kingston, by steam, - - -	5s. 0d.
Ditto to Coburgh, or Port Hope, - - -	7s. 6d.
Prescot to Toronto, capital of Upper Canada, Hamilton, and Niagara, - - - - -	10s. 0d.

From Niagara you proceed by the Welland Canal to Fort Erie, opposite Buffalo on Lake Erie, where steam-boats, or sailing schooners, will convey those destined to Port Talbot, or other parts of the London district, or vicinity of Lake St Clair. Persons going to settle on the lands of the Canada Company will proceed to York or Burlington Bay, head of Lake Ontario.

At most of the preceding towns and landing-places you will find government agents. If you are bound to Perth, or New Lanark, or the vicinity, disembark at Prescot; or you may go by Bytown on the Ottawa.

If for the thriving settlements in the Newcastle district, disembark at Coburgh or Port Hope, on Lake Ontario. Those going to the townships of Seymour may proceed from Kingston, by the beautiful Bay of Quinte, to the mouth of the Trent River, from whence a road, distance 18 miles, leads you to Seymour. If proceeding to the Home or Western districts, disembark at Toronto, the capital of Upper Canada. Emigrants going any where beyond Toronto, will in general find it their interest to take this their route. If for the London district, proceed by the Niagara frontier to Lake Erie and the Talbot Settlement. If for Bytown, Grenville, Hull, Horton, or other situations on the Ottawa River, proceed from Montreal and Lachine by the usual conveyances. Such are the directions that were a short time since suitable; but as there are continual changes, emigrants may find it necessary, on their arrival, to act more by local information than any thing we can say on the subject.

We think it important to mention, for the benefit of the poorer class of emigrants, that there has existed for some years in Montreal a benevolent society of great use and importance, called the Canada Emigration Association. This body of individuals, actuated by humane motives, and anxious to forward labourers to places where their services are required, affords ready assistance to poor emigrants on their arrival at Montreal. It appears that, from the 15th of June 1840 to the close of the navigation by frost a few months later, the society received 2,000 natives of England, 877 natives of Ireland, 1,773 natives of Scotland, and 210 from Germany; total, 5,067. Of this number, 201 were above sixty years of age, and 547 were infants. The relief consisted in furnishing provisions and a humble kind of lodging in sheds, also medical attendance, and payment of passage of themselves and families to places in the interior. The emigrants were greatly benefited by being sent off without loss of time, as they were thereby not only saved from the danger to their health and morals which would have been incurred by remaining any length of time in a large city, but their time was

s from selecting this province as their home. It
ed that nearly all the lands within the settled
ts of the province have passed into the hands of
e individuals; and that the new emigrant must
arily go far into the depths of the forest, remote
the peopled settlements, where, whatever may be
xcellence of his land, he will be remote from
ds, mills, roads, or the means of procuring labour
plies, during the first years of his residence.
se difficulties have existed to a great and dis-
ssing extent, sometimes so as to induce a settler
ndon his possessions. It is true, also, that a great
rtion of the land, especially in the older surveyed
ships, comprehending the choicest locations in the
neighbourhood of roads and navigable waters, now be-
to private individuals; and it is this very fact
nables the association to be of the most essential
e. These tracts are at present unproductive to
wner, and if retained in their wild state, with the
e their owners' obtaining higher prices, would in-
e such a serious obstacle to the settlement of the
ry, as might well justify the legislature in impos-
tax upon lands kept unimproved from so selfish
narrow a policy. The association are happy in
ng, for many of such proprietors are among its
zealous members, that such lands generally re-
e their profitless fertility, only because the hand
n is wanting to turn them into productive corn-
and animated pastures; and that, if their fellow-
rymen were here to make use of them, they would
ppy in giving to them portions equal to their
t wants, without money and without price; yea,
very other aid which could tend to their future
tage. And this, too, without any affectation of
sity on the part of the members of the associa-
for they are well aware that, by the settlement and
ation of a portion of their lands, the adjoining
will become better worth the purchasing by future
ants, or by the settler himself, when he shall have
e prosperous.
e system of free grants of portions of private pro-
e scattered over the whole province, and therefore
nting endless choice of locality, in respect to pre-
settlement of friends, &c., to such persons as have
ney to pay, or having small means, might, more
cially to themselves and the country, apply them
elerate the improvement of the land, forms the
pal feature in the scheme of the association, by
they hope to be useful to their countrymen. But
nly one: there are cases where not only the poor,
ven the comparatively affluent settler, has had to
nter difficulties which might well dishearten him,
ven drive him to abandon his enterprise. Many
bers of this association have had practical know-
of the evils which they are now intent upon avert-
om others; and are desirous of giving their ex-
nce without its price. The establishment of their
try-Office for the sale of lands not devoted to the
-stated object, and for supplying accurate infor-
n, statistical and otherwise, will be found of great
o such as are beyond the necessity of receiving
ther kind of assistance; while, in locating those
shall be disposed to accept of their land, they will
ally avoid the evil before mentioned, of sending
where they will be isolated and solitary, but under
an arrangement as will ensure to each the com-
of society while he is engaged in the first, and in
ses the most discouraging task he has to encoun-
subduing the forest."

e may learn from these extracts that the Cana-
are now fully alive to the necessity of procuring
dy supply of labourers as well as settlers to clear
rounds, by which alone the country can be ex-
d to develop its great resources.

migrants, on arrival, will find no difficulty in discovering
mes and places of abode of the agents of the Immigration
y: they are settled in most towns of the province, and we
doubt that they will give friendly advice and assistance to
o present themselves.

place called Galena, on the Fever River. Salt is also manufactured extensively at Shawneetown in Gallatin county; and other salt springs have been discovered in different parts of the country. The climate of Illinois does not differ very materially from that of the other states in the same latitude; from its lower situation it is perhaps generally milder. In the southern parts the winter is said seldom to exceed six weeks; in the northern parts, again, it is sometimes very severe, but not of long duration. Settlers on their first arrival are apt to be attacked by bilious fever, but with proper care as to clothing and diet this may be avoided. A disease called the *milk sickness* frequently attacks the cows in this country, and has even proved fatal to man, from drinking the milk of the diseased animals. It is supposed to be caused by the cows eating the leaves of a poisonous grape, which might be easily prevented by rooting out the plant from around a farm.

Mr Shirreff speaks very highly of this country as a field for emigration; being of opinion that there is no country in the world where a farmer can commence operations with so small an outlay of money, and so soon obtain a return. This arises from the cheapness of land, and the facility with which it may be cultivated, there being little or no forest land to clear. Mr Shirreff makes a statement of the expense of purchasing 200 acres of land, fencing forty acres, ploughing and sowing eighty, harvesting, building houses, and maintaining family, which he estimates at 1604 dollars, equal to L.340, 17s. With this expenditure is obtained the dairy produce of four cows, the improvement of eight cattle grazing on the prairie, and 3200 bushels of Indian corn, besides vegetables, and the improvement of pigs and poultry. Next year, the settler might plough eighty acres more; and in eighteen months after settling, would have expended L.484, 4s., and reaped 6400 bushels of Indian corn, and 1600 bushels of wheat, besides abundance of vegetables, dairy produce, beef, pork, and poultry. In this statement, Mr Shirreff has stated the produce at 22½ bushels per acre, which is lower than what he was told land in Illinois generally yields. He supposes, also, that the farmer and family only attend to the cattle; the ploughing, &c., being performed by contract. In the case where the farmer himself works, he estimates the purchasing, fencing, ploughing, sowing, &c., of eighty acres at 609 dollars, or L.130 sterling; and for this the farmer reaps 2400 bushels of Indian corn, 675 bushels of wheat, and receives the dairy produce of one cow, pigs, and poultry, besides abundance of vegetables.

Grazing is extensively carried on in the prairies of Illinois, the cattle being sent to New Orleans in great numbers. "With an unlimited range of pasturage for the rearing of cattle," says Mr Shirreff, "and Indian corn at 15 cents, or 7½d. per bushel, the farmer might comfortably live by stock without cultivating any portion of land."

The capital of Illinois is Vandalia, which is situated on a high bank of the river Kaskaskia, in the midst of a rich and thriving country. There are also several other towns rapidly rising into importance, such as Edwardville, Carlisle, Kaskaskia, &c. The state of Indiana resembles Illinois, but contains a greater portion of waste land. The land is mostly all prairie, and the country is well watered by numerous rivers.

Missouri.—The state of Missouri is separated from Illinois by the river Mississippi, which flows along its east and north-east sides. It contains considerable diversity of soil, being in one part hilly, and in others marshy; but for the most part it is good prairie land. Its means of internal commerce are great, from the Missouri and other rivers flowing through it. Mr Flint says of its soil—"This state possesses lands already fit for the plough, sufficient to produce wheat enough for the whole of the United States. Prairies of hundreds of thousands of acres of first-rate wheat lands—covered with grass, and perfectly free from shrubs and bushes —*invite the plough*; and if the country were cultivated *to a proper extent, it might* become the granary of the world." The climate of this state is changea winters are sometimes very severe, and the s extremely warm. In several parts of this climate is unhealthy, owing to swamps and la in the mountainous tracts the inhabitants en health. The staple agricultural productions a and Indian corn, with the usual fruits of wa tries. Cotton is cultivated in the south-east along with tobacco; and hemp and flax are l important articles of produce. This state l long celebrated for the immense deposits of found amongst the hills. There is one district ing over nearly one hundred miles, which is larly distinguished for its lead mines. The ore imbedded in masses, and appears evidently to posit. Coal is also found in several parts of as also iron ore, manganese, zinc, &c. The ch in Missouri is St Louis, pleasantly situated on vation close to the Mississippi. It is a thrivi rapidly rising to importance, being the port all vessels arrive from New Orleans, &c.

The Count Marbois thus speaks of the stat valley of the Mississippi:—"At the junction Mississippi and Missouri, the lands lying tow north-west are of admirable fertility; and th tricts, though remote from the sea, will one d densely populated as any portion of the wor Mississippi, the Missouri, the Arkansas, the Re and their tributaries, water 200,000 square within the space of country called the valle Mississippi. This internal navigation, prep nature, has already been greatly extended and i by canals, and steam-boats ascend and descend wind and tide with great speed. Wood and dispensable agents in this navigation, abound shores of the rivers, supplying steam-ships means of traversing this magnificent stream."

These states, from the facility of communicat be reached from any of the great ports of th The route by New Orleans is recommended cheapest, from the number of steam-ships wh constantly plying between that port and St the Missouri. The cabin passage from Live New Orleans is L.35, and the passage from leans to St Louis L.5, 6s., including provisi steerage passage is from L.4 to L.5 to New and L.1, 14s. to St Louis, exclusive of provisio

Michigan.—The reader will observe on the tongue of land, situated between the two lakes, and Michigan; this tract, with another whic the west, between Lake Michigan and the Mis has been lately begun to be settled by emigra the old states of America. The two together great recommendations to agricultural emigra capital is Detroit, a town situated on the rive connects Lake Huron with Lake Erie, and co 2500 inhabitants. These lakes, with their riv canals, give the district access to the markets York, New Orleans, and Montreal.

The climate is temperate and healthy: win in generally about the middle of November, a tinues till about the middle of March. At De 1818, the mean heat of January was 24°; and the mean heat of July was 69°, of December 27 country is situated upon limestone rock, rath and possesses what the Americans call good wa vileges—that is, numerous falls of water for m It is better watered than any other in the States, being finely diversified with lakes and rising in most parts from copious springs.

The soil is in general a good fertile loam, up stone: in some places a calcareous earth is tu mixed with the common soil; in others, the mixed with a little sand; both are extremely tive. The country is, in some districts, unde timber, and in others an open prairie, where th has nothing to do but start his plough. Hor here from L.18 to L.22, 10s.; oxen from L.15 a-pair. The produce of the land runs from

cipal districts in the western country are
ana, and Illinois. There are considerable
ed in each of these, the most advantageous
those likely to become important in the
of the country, having been immediately
n for that purpose. Some of these have
longer in existence than fifteen years; few
cept those on the river Ohio, longer than
, from the influx of new settlers, and the
e find in maintaining themselves and their
ch places are already populous and thriving.
y is generally flat, so that the towns do not,
of the western states, owe their origin to
situations for water-power. Manufactures,
&c., if ever established here, must derive
r from steam; for which, indeed, the abun-
nal offers great facilities, while the smooth
he numerous rivers makes the mines avail-
he whole district.

ti, a town situated on the Ohio, on the con-
two states, Indiana and Ohio, is a place of
e. In 1800, it contained only 750 people,
15 only 960; it was then surrounded by a
ry, occupied by the Indians. The country
now cultivated, and the number of inhabi-
e town is about 35,000, composed of people
arts of Europe and the United States, who
attracted by the advantages of the place.
osite side of the Ohio, in the state of Ken-
e is another town, which is divided into two
e Licking; these two parts are laid out on
egular plan as Cincinnati, so that the whole
appears one city. There are many great manufacturing works here—steam-mills, glass and iron works, &c., and the bustle of the place gives the farmers an excellent market for their produce. This advantage is further increased by the trade of the numerous large steam-boats which here take in cargoes of beef, pork, flour, &c., for their voyage down the Ohio and Mississippi to New Orleans. Formerly, they could not easily ascend the river, on account of rapids which occur farther down at Louisville; but these have been now overcome by a canal two miles in length, cut through the rock at that place. Louisville itself is situated in Kentucky, and is a place of considerable trade.

Other large towns in this tract of country are Pittsburg, Wheeling, Steubenville, Marietta, and Chilicothe. They afford a considerable market for agricultural produce; and the free navigation to New Orleans, as well as the facilities now afforded by a canal cut to intersect the country from the Ohio, at Portsmouth to Cleveland, on Lake Erie, secure a constant and steady demand for grain, salted beef, pork at the mall, &c. The Americans look forward to this district, and the vast countries surrounding it, as the future pivot of their national grandeur.

The countries in the valley of the Mississippi include Illinois, Indiana, and Missouri, to which we shall now advert.

Illinois and Indiana.—The tide of emigration has for some time back been setting towards the west countries, and amongst these Illinois is conspicuous for its great extent, and the general fertility of its soil. This state is 382 miles long and 154 broad, with an area of 58,900 square miles. It is bounded on the north by the Wisconsin or north-west territory, on the east by Lake Michigan and Indiana, on the south by the Ohio, and on the west by the Mississippi. The whole country is described as a very gently inclined plain, very level—no height reaching above 600 feet. It is nearly all prairie, with a few groves of timber widely separated from each other, and deeply indented with ravines whose sides slope into low round hills. Illinois is favourably situated with regard to water communication. On one side it has the Mississippi as its boundary, on another side the Ohio and Wabash; to the north it is washed by Lake Michigan. The Illinois, from which the state receives its name, connects Lake Michigan with the Mississippi; Rock and Kaskaskia are also navigable rivers; and besides these there are numerous boatable streams.

The soil of this state resembles that of Ohio, but with less irreclaimable land. On this subject Mr Shirreff says—"The soil of Illinois is variable, and the different habitations of the varieties of the sun-flower, and other tall-growing plants, often distinctly marked changes of soil on the prairie. The prevailing soil between Chicago and Springfield was black sandy loam, and occasionally considerable tracts of clay or heavy loam intervened. In this distance of nearly 200 miles, I did not pass over in all ten miles of bad soil, which was light-coloured sand. The surface, which is forest, oak openings, or prairie, has no relation to quality of soil, all of which abound with soils of every description." These prairies are covered with grass three or four feet high, which is burned annually, either being set on fire wilfully or igniting from natural causes. No danger is apprehended from this burning, the ploughing of the ground around a dwelling being sufficient to prevent the fire from spreading so far, and the grass, being perennial, comes up again in spring.

The productions of Illinois are Indian corn, wheat, potatoes, cotton, hemp, flax, &c. Fruits, such as the grape, apples, peaches, gooseberries, &c., arrive at great perfection, and the silk-worm has been found to succeed well. In the wooded parts, the trees exhibit a luxuriant growth, and are often seen of an enormous size. The mineral productions are of great value, consisting of lead, coal, copper, and lime, and good building stone. The lead-mines, which were opened in 1821, are situated in the north-west corner of the state, at a

ought to avoid as a set of leeches. Americans may deal in those matters, and may perhaps profit by them; but emigrants never can do any thing but involve themselves in difficulties by such schemes. Let them look to *certainties exclusively*; the quality of the land, the healthiness of the site, the neighbourhood of a market already established—these are the only considerations that should weigh with them, and no other. In short, to those who have capital, we would say, without hesitation, choose your abode near some of the principal towns; it is almost indifferent which. The soil of the western countries on the Ohio is the richer, and its produce more varied and luxuriant, but the prices of agricultural produce are lower than in the old states, and labour dearer. This is the sole and essential difference, except, indeed, to those who wish to speculate in buying land, by adding to its improvements, and then selling it at a higher rate, when their own labour, and the increasing density of the busy population around them, shall have added to its value. To persons who wish to make money in this way, the vicinity of the rising towns in the western states is certainly a field of high promise, and many have already realised large sums there by proper management in that manner.

Mechanics, Farm-Servants, and Labourers.—Mechanics and labourers, in looking for a situation where they may settle, will be guided by very different views from those of persons possessed of capital. The latter, if they wish to buy land, will prefer to have it in a place where labour is cheap, and farm produce sells dear. The man who lives by his wages, on the other hand, would have labour high, and all manner of provisions cheap. We have advised those possessed of capital to look for settlements as near the large towns as possible, where markets and labour are most easily procured. In regard to the places to be chosen for settling by mechanics, farm-labourers, and others who look for work, we believe, that to those who possess funds sufficient to carry them forward to the western or inland states, there can be no doubt but these afford the preferable field for them, both in respect to wages and cheapness of living. The towns on the Ohio are all gaining rapidly in population and importance, from the richness of the country with which they are surrounded; and many considerations make it probable, that if manufactures be ever largely established any where in America, it will be here. The carriage of foreign manufactured goods is very expensive to a country so remotely inland, and to which they have to be carried through so many canals, rivers, or railroads; and the district itself produces cotton, silk (if cultivated), iron, lead, coals, &c.; so that there is here a *bonus* for manufacturing on the spot which hardly any other country possesses. The consequence begins to be already felt: manufacturing establishments are begun, wages are high, and the price of living is withal exceeding low. To mechanics and labourers, therefore, who have money to defray the expenses of the journey, we cannot but say that the western states present by far the most favourable opportunities. The following extract of a letter is from Cincinnati, on the Ohio:—

"The improvements in Cincinnati are rapidly increasing: the communications opened by means of the canal and the new roads give an impetus to trade. Whatever number of artisans, mechanics, and labourers come out, they will find abundant occupation. The soil is excellent. Engineers are in great demand. Engravers, particularly those who will work in general work, as maps, names, &c.; card-manufacturers; tinmen and braziers; bell-hangers, with a knowledge of casting or directing in that department; baking, brewing, and malting; are good trades. Glovers, stocking-weavers, first-rate plane-makers, turners in steel, iron, brass, and wood, are much wanted. Carpenters, joiners, builders, plasterers, bricklayers, stone-masons, plumbers, all who *are good at their business*, and labourers, can get plenty *of work, at 3s. or 4s. per day.* Gardeners and mechanics average 4s. 6d. to 9s. per day, curriers, 9s. journeyman's wages. Tailors get 20s. for a coat. Hatters do well."

On the subject of wages Mr Shirreff says—"dustrious and sober man must rapidly acc wealth by working for hire, and many perhaps purchasing land instead of continuing to wo the direction of others. On leaving New gardener, who was working at Haddington wh Scotland, gave me ten pounds sterling, whic saved since his arrival in America, to enable and family to reach him. A young man who often employed at spade work at 1s. 6d. a-day, ing by sawing stones at Cincinnati 4s. 3d. a-d board."

Let it be recollected, that, with these wages at 9s. per 112 lbs.; mutton at 2d. per lb.; sug 5d. per lb.; coals 5d. per bushel.

It may now be asked, what additional exp be required to take a mechanic to Cincinnati, has reached New York or Philadelphia? To find it answered, that the journey from New Wheeling (a town on the Ohio) costs 25 do L.5, 12s. 6d.; and from Wheeling to Cincin steam-boat on the Ohio, the fare is 10 do L.2, 5s. The whole expenses, therefore, fr York to Cincinnati, are L.7, 17s. 6d. The jour now be made, by the canals and steam-boats, to on Lake Erie; thence to Cleveland; and fr place, by the canal, to Cincinnati. This wil the expense somewhat. The same letter fro we have quoted above, mentions, that a fami spectable persons had arrived at Cincinnati fr land, and that the whole expense of their journ 2500 lbs. luggage) was L.75. But there is no for going even so far as Cincinnati—Wheeling Pittsburg, which, though still on the Ohio, nearer New York, present quite the same indu to mechanics of all descriptions.

Labour is in the greatest demand every whe people are not able to avail themselves of the the country which they inhabit without assistan Flint, who travelled on foot, was stopped by the asking him anxiously if he "*knew of any trave would rest himself, and thrash for a few days;*" Stuart of Dunearn, after telling one of the Ohio the work usually done by farm-servants in S was charged, on departing, not to neglect sendi of them to America, if possible.

It is not in one or two districts of the Un this demand for work-people exists, but every The towns immediately on the coast are g better supplied with tradesmen, labourers, & those inland, because emigrants first land the often apply for employment as soon as they go o but in all that we have heard on the subject, no instance of a person who was willing to wo who did not find employment.

Persons who wish to buy small lots of land.—emigrants possessed of good capitals, there a men who are acquainted with farming busin with that only, but who have not money to buy it land, and who wish, therefore, to depend on th industry for clearing ground for themselves. such men, after persevering for years, with the lies, in unrequited labour in this country, have America, and become proprietors of well-impro rich farms. We could quote numerous exam this kind: the following is from Mr Flint's int publication:—"J. M., a man from the county burgh, arrived here (near Pittsburg), and had with his family, seven sons, two daughters, an in-law, about ten months before I met him. purchased 480 acres of land; built two log-hou a small stable; cleared and enclosed about two acres, which are nearly all under crop; deade timber of about eighty acres more; and pla orchard. In addition to these improvements, have wrought for a neighbour to the amount o

heat, after one bushel of seed. The cotton ape vine, the sweet potato of Carolina, the egg-plant, have all been successfully cul- e, barley, oats, peas, beans, and potatoes, l kinds of vegetables usually cultivated in titude, produce here in great abundance. pears have been tried, and both produce it: near towns, pears sell at from 2s. to 4s. apples vary from 6d. to 2s. per bushel; ackberries, raspberries, and strawberries, dingly. Indian corn is less luxuriant than of the Ohio, the climate being somewhat is country, on the whole, seems more con- ıropean constitutions and habits than the n settlements.

st and perhaps most beautiful part of the generally thought to be that adjacent to ɔh's River, on which twelve new counties The soil is excellent, and there are nume- water, for mills, &c.

f the government land-offices (which are wherever there is land to sell, in all the ttler may provide himself with a farm, at te of 5s. 7½d. per acre. No quantity smaller s is sold by government. Should he chance in some favoured spot (most of which are red along the great public road for 300 h the country), he will have little difficulty it for 12s. or 15s. an acre. An extensive ntry upon the river and bay of Laganaw side of Lake Huron) is spoken of in terms ıiration for the richness of the soil and e natural scenery, and also as presenting nducements to enterprising and industrious mechanics, from its central and advanta- n for business. The river Laganaw is navi- ıts, twenty miles from the head of the bay, s made to Detroit. Fox River, on the west Michigan, is also specially noticed as highly settlers, in regard to quality of soil, beauty, rantages: a canal is projected to connect ıd the lake with the Mississippi.

sson, to whom we are indebted for the above gives an estimate, from the experience of ıainted with the district, of a purchase in ıd of its returns:—

nce is here made for maintenance; but it ɔollected, that the wheat crop may be re- hree or four years without manure, and in ing years the charge for purchase disap- ıt the advantages of the latter are obvious. roperly appreciated by the Americans, the emigrants flocking to Michigan being im- population in 1831 was estimated at 32,000. ıe capital of Michigan, is the embryo Con- ɔf the inland seas of North America. It is ı narrow channel, which connects the two Ontario and Erie, with the three upper, ıigan, and Superior. Having access in every countries of more fertile soil than those of sia, and possessed of an equally favourable egins its career with political institutions ropitious to human welfare than were pos- e celebrated city we have mentioned; and one day to be the abode of a more nume- as happier population.

Other Districts.—The three districts we have mentioned are those in which the greatest quantities of land are yet unoccupied, and where it is to be had cheapest; but there are others in which settlers may locate themselves with advantage. Among these is the district of Genessee, in New York state; and, indeed, the whole valley of the River Hudson presents, at intervals, spots on which good land may be purchased, especially by those who would rather sit down on a place partially cultivated, and near markets, than in the heart of the forest.

DIFFERENT CLASSES OF EMIGRANTS.

Men with Capital.—There are three different classes of emigrants, each of whom will be guided by different motives in their choice of a situation. The first is composed of persons who are possessed of capital to some amount, and who have been accustomed to move among the wealthier classes of society in this country. If these individuals intend to devote themselves to agriculture in the country to which they are bound, every circumstance leads us to believe, that unless they are prepared to submit to very great sacrifices of personal comfort, and that for no inconsiderable time, they ought to purchase land partly improved, and as near some of the towns as they can find it. The hardships of a new settlement to persons who have not been accustomed to labour, are hardly such as can be anticipated by description; while the total change of habits—labouring in the woods, living in log-huts, and the want of regular food—often induces disease, of which such persons may feel the effects during the whole of their after lives. Abundance of half-improved properties may be found (as we have mentioned under the title Purchasing of Land), upon which moderate labour, and the exertion of some skill and attention, will secure excellent returns. These may be heard of at any of the large towns, but chiefly at New York, or at Albany, Genessee, Rochester, Geneva, &c., in that state. In Philadelphia, also, in the state of Pennsylvania, most eligible purchases of this kind may be made; and at Pittsburg, a very busy manufacturing town in the same state, on the river Ohio, there are many properties on sale which must rise in value every day with the increasing commercial importance of the place. There are immense beds of coal, iron ore, and limestone, in the vicinity of the town, and the navigation of the Ohio is uninterrupted (though there are some inconsiderable rapids) the whole way to its junction with the Mississippi. Communications by canal and railroad are also now completed, to connect the Ohio at this place with Baltimore and Philadelphia, so that the town of Pittsburg is already of great wealth, and promises rapidly to increase. The land in the neighbourhood is of uncommon fertility, and may be obtained now at prices lower than can be expected in a few years, when a greater number of settlers shall have arrived to occupy it. Properties within twenty miles of the town already sell very high—say fifty dollars or more. Almost the same observations may be made with regard to Louisville, Cincinnati, and Jeffersonville, which are situated in the states of Ohio, Kentucky, and Indiana; these places already possess great trade, and from the abundance of minerals, coal, lime, iron, salt, and lead, which are found in the neighbourhood, they must continue to increase. Farms, therefore, purchased in their vicinity, are certain to rise in value, and, with attentive cultivation, will, in the mean time, pay the cultivator abundantly for his labour and capital. Cincinnati particularly is a place of great activity, and persons who settle in its neighbourhood will easily find society to their liking; it presents, indeed, though so remote from European cities, no difference nor any inferiority in this respect. It is right to mention, however, that the whole of the western country, and, indeed, of all the countries which are in progress of settlement, are overrun with a swarm of speculators in land, and in projected establishments, new cities, manufactories, &c., all of whom the monied emigrant

ought to avoid as a set of leeches. Americans may deal in those matters, and may perhaps profit by them; but emigrants never can do any thing but involve themselves in difficulties by such schemes. Let them look to *certainties exclusively*; the quality of the land, the healthiness of the site, the neighbourhood of a market already established—these are the only considerations that should weigh with them, and no other. In short, to those who have capital, we would say, without hesitation, choose your abode near some of the principal towns; it is almost indifferent which. The soil of the western countries on the Ohio is the richer, and its produce more varied and luxuriant, but the prices of agricultural produce are lower than in the old states, and labour dearer. This is the sole and essential difference, except, indeed, to those who wish to speculate in buying land, by adding to its improvements, and then selling it at a higher rate, when their own labour, and the increasing density of the busy population around them, shall have added to its value. To persons who wish to make money in this way, the vicinity of the rising towns in the western states is certainly a field of high promise, and many have already realised large sums there by proper management in that manner.

Mechanics, Farm-Servants, and Labourers.—Mechanics and labourers, in looking for a situation where they may settle, will be guided by very different views from those of persons possessed of capital. The latter, if they wish to buy land, will prefer to have it in a place where labour is cheap, and farm produce sells dear. The man who lives by his wages, on the other hand, would have labour high, and all manner of provisions cheap. We have advised those possessed of capital to look for settlements as near the large towns as possible, where markets and labour are most easily procured. In regard to the places to be chosen for settling by mechanics, farm-labourers, and others who look for work, we believe, that to those who possess funds sufficient to carry them forward to the western or inland states, there can be no doubt but these afford the preferable field for them, both in respect to wages and cheapness of living. The towns on the Ohio are all gaining rapidly in population and importance, from the richness of the country with which they are surrounded; and many considerations make it probable, that if manufactures be ever largely established any where in America, it will be here. The carriage of foreign manufactured goods is very expensive to a country so remotely inland, and to which they have to be carried through so many canals, rivers, or railroads; and the district itself produces cotton, silk (if cultivated), iron, lead, coals, &c.; so that there is here a *bonus* for manufacturing on the spot which hardly any other country possesses. The consequence begins to be already felt: manufacturing establishments are begun, wages are high, and the price of living is withal exceeding low. To mechanics and labourers, therefore, who have money to defray the expenses of the journey, we cannot but say that the western states present by far the most favourable opportunities. The following extract of a letter is from Cincinnati, on the Ohio:—

"The improvements in Cincinnati are rapidly increasing: the communications opened by means of the canal and the new roads give an impetus to trade. Whatever number of artisans, mechanics, and labourers come out, they will find abundant occupation. The soil is excellent. Engineers are in great demand. Engravers, particularly those who will work in general work, as maps, names, &c.; card-manufacturers; tinmen and braziers; bell-hangers, with a knowledge of casting or directing in that department; baking, brewing, and malting; are good trades. Glovers, stocking-weavers, first-rate plane-makers, turners in steel, iron, brass, and wood, are much wanted. Carpenters, joiners, builders, plasterers, bricklayers, stone-masons, plumbers, all who are good at their business, and labourers, can get plenty of work, at 3s. or 4s. per day. Gardeners and mechanics average 4s. 6d. to 9s. per day, curriers, 9s. p journeyman's wages. Tailors get 20s. for ma coat. Hatters do well."

On the subject of wages Mr Shirreff says—" dustrious and sober man must rapidly acca wealth by working for hire, and many perhaps purchasing land instead of continuing to work the direction of others. On leaving New Y gardener, who was working at Haddington whe Scotland, gave me ten pounds sterling, which saved since his arrival in America, to enable h and family to reach him. A young man whom often employed at spade work at 1s. 6d. a-day, wa ing by sawing stones at Cincinnati 4s. 3d. a-da board."

Let it be recollected, that, with these wages, at 9s. per 112 lbs.; mutton at 2d. per lb.; suga 5d. per lb.; coals 5d. per bushel.

It may now be asked, what additional expe be required to take a mechanic to Cincinnati, has reached New York or Philadelphia? To find it answered, that the journey from New Wheeling (a town on the Ohio) costs 25 doll L.5, 12s. 6d.; and from Wheeling to Cincinn steam-boat on the Ohio, the fare is 10 doll L.2, 5s. The whole expenses, therefore, fro York to Cincinnati, are L.7, 17s. 6d. The journ now be made, by the canals and steam-boats, to on Lake Erie; thence to Cleveland; and fro place, by the canal, to Cincinnati. This will the expense somewhat. The same letter fro we have quoted above, mentions, that a family spectable persons had arrived at Cincinnati fro land, and that the whole expense of their journe 2500 lbs. luggage) was L.75. But there is no for going even so far as Cincinnati—Wheeling Pittsburg, which, though still on the Ohio, nearer New York, present quite the same induc to mechanics of all descriptions.

Labour is in the greatest demand every wher people are not able to avail themselves of the r the country which they inhabit without assistan Flint, who travelled on foot, was stopped by the asking him anxiously if he "*knew of any travel would rest himself, and thrash for a few days;*" Stuart of Dunearn, after telling one of the Ohio the work usually done by farm-servants in S was charged, on departing, not to neglect sendi of them to America, if possible.

It is not in one or two districts of the Uni this demand for work-people exists, but every The towns immediately on the coast are g better supplied with tradesmen, labourers, & those inland, because emigrants first land the often apply for employment as soon as they go or but in all that we have heard on the subject, no instance of a person who was willing to wo who did not find employment.

Persons who wish to buy small lots of land.—emigrants possessed of good capitals, there a men who are acquainted with farming busine with that only, but who have not money to buy in land, and who wish, therefore, to depend on th industry for clearing ground for themselves. such men, after persevering for years, with the lies, in unrequited labour in this country, have America, and become proprietors of well-impro rich farms. We could quote numerous exam this kind: the following is from Mr Flint's int publication:—"J. M., a man from the county burgh, arrived here (near Pittsburg), and had with his family, seven sons, two daughters, an in-law, about ten months before I met him. purchased 480 acres of land; built two log-hou a small stable; cleared and enclosed about twe acres, which are nearly all under crop; deade timber of about eighty acres more; and pla orchard. In addition to these improvements, have wrought for a neighbour to the amount of

ork. He has a horse, a cow, a few hogs, ultry. I inquired if he felt himself happy land. He replied, that he would not re- and, though the property of which he for- a part were given him for nothing."
nce—and hundreds of others might be show that people from this country, with m L.50 to L.100, may establish themselves ica. Smaller sums than these will hardly l with, if the settler intends to buy land because eighty acres of land (which is the y sold by government) costs L.22, 10s.; omething were done to raise a crop the the other expenses of a log-house, &c., every thing. The price of government ed to be paid immediately.
ng quotation affords a graphic description n and life of cultivators in the woods:— in the woods appear to be the most con- dependent people, in their way, I ever met s with only a log-house, unplastered, con- ooms, one above and one below, sometimes w, with a large open fire-place, and a log- nney back and hearth built of stone, picked farm; a boarded floor unplaned, perhaps if too far from a saw-mill; one or two sh windows, and sometimes at first none; es with wooden hooks and hinges. A few mon household use; two spinning-wheels, nd one for wool, with reaves of spun-yarn the inside of the house on wooden pegs, ie logs; an upright churn; a rifle-gun; a an oven out of doors, at a little distance use, built sometimes of clay, sometimes ones, often placed on the stump of a tree e, and with a shed covered with tree bark '; a yoke of oxen, some young steers, two , eight or ten sheep; perhaps a horse, or ; a sleigh waggon, a plough and harrow, ps with wooden teeth; these form all their their land, and on this they often raise or two hundred bushels of wheat, eighty ed of Indian corn, some oats, peas, and wheat and a patch of flax; and fatten hogs and a cow, or a yoke of oxen in a s seven or eight more store pigs, and a Those who brought a little money with e fortunate in having a family of indus- et perhaps a good frame house, or, at all l frame barn, eighty or one hundred acres ed; grow four hundred or six hundred heat; other things in proportion; with yoke of oxen, twelve to thirty fat hogs, orses, &c., half of them or more brood

ing is a ruder picture of industry:—"In unty (Illinois) one of our frontier men lf on government land three or four years our or five sows for breeders, worth as . In 1829, he drove forty-two fat hogs to h he sold for 135 dollars (£30, 7s. 6d.) of corn given to the whole before he drove ; exceed one bushel. They lived on the ew fat on *mast*, that is, beech-nuts, wal- &c.; had they been fed on corn they old higher. Of the proceeds, 100 dollars ere applied to pay for eighty acres of land had settled; the remainder served to pay lebts, and to purchase his salt, iron, and the year. This is not an extraordinary ut one common in that country."

PURCHASING LANDS.

il recently, the practice of the American o sell the public lands on credit, receiving nstalments; but this plan was found so hat it has been abandoned, and the pub- now sold for cash only. While the credit operation, many people were induced to become proprietors of large tracts of land which they had not the means of cultivating, and in the course of a few years the land again fell into the hands of government. The farmer was thus left in a worse state than when he first settled in the country; his capital was expended without having yielded him any suitable return. Most travellers concur in representing the cash system as much superior to the former practice of giving credit, for by it, although any person should be foolish enough to purchase land without having the means of cultivating it, his capital is not lost, as he may always get the price he paid for it again. In the United States there are public land-offices in the chief towns, at which maps of the sold and unsold lands are kept for inspection. Lands are first offered for sale by public auction, and are put up at from a dollar and a quarter to two dollars per acre. If no one offers these prices, they are exhibited on the land-office map, and may be obtained at any subsequent period. On the maps, sections of a square mile, and quarter sections of 160 acres, are laid down; six miles square constitute a township. The sixteenth section of each township is reserved for the support of a school. The deed which confers the right of property in the States is very simple. It is printed on a piece of parchment of the quarto size; the date, the locality of the purchase, and the purchaser's name, being inserted in writing, and the instrument subscribed by the President of the United States, and the agent of the general land-office. It is delivered to the buyer free of all expense, and may be transferred by him to another person without the intervention of stamped paper, law practitioners, or those absurd feudal usages which continue to disgrace the transfer of landed property in Great Britain. Emigrants in going into the woods to make a selection of lands, will do well to take with them an extract from the land-office map applying to the part of the country they intend to visit, and by this they will discover entered from unentered lands.

The public land is, of course, totally uncleared, and untouched by the plough; some of it is more heavily timbered than other portions, and it is of very various quality, that on the banks of rivers and alluvial grounds being exceedingly fertile, and other parts being either rocky or marshy, so as to be either too unhealthy or too unprofitable to be cultivated. The settler, however, has his choice, and, by going out into the woods, he may fix upon a lot to his own mind. An enterprising cultivator, particularly if he be a stout man, with a family of sons, may do very well upon such lands, because the original price is small; and after clearing them to some extent, and erecting one or two log-houses and barns, he can either extend his cultivation (which is easy after crops are got for the first three seasons), or he may sell at a considerable advance as population begins to increase around him, and as settlers arrive, who are not inclined to make first beginnings in the woods for themselves.

When lots are advertised for sale, there are persons who make it their business to go out to survey the whole tract before any one else has examined it; and by remaining in the woods for months, sleeping often in the open fields, and undergoing great hardships, they get acquainted with all the natural advantages of the land, the spots where there are water-power, minerals (such as salt springs, &c.), healthy, open, or fertile grounds, and select such of these as they choose, in order to sell them again at a profit. This practice raises the price of the best lands, and it is one which can only be followed by natives well acquainted with the face of the country; but it cannot be said to have much effect in retarding settlements, as the persons who follow it seldom have very large capitals, and are soon willing to dispose of their purchase at a reasonable advance to those who intend really to avail themselves of the natural advantages which the former have been at the trouble to search out.

In 1838, 12,251,966 acres of land were offered for sale, of which quantity 1,388,733 acres were sold; the

price paid being 1,749,401 dollars, or about 1¼ dollar, (5s. 7½d.) per acre. At the commencement of 1832, the quantity of land unsold, and to which the Indian title had been extinguished, in the states of Ohio, Indiana, Illinois, Missouri, Mississippi, Alabama, Louisiana, and Michigan, and in the territories of Arkansas and Florida, was estimated at 227,293,884 acres. The quantity in the same states and territories held at that period by the Indians was estimated at 113,577,869 acres. The quantity beyond these states and territories was estimated at 750,000,000 acres; making the whole of the public lands at the commencement of 1832, 1,090,871,750 acres.

These are the public lands, but there are vast quantities of ground in the hands of individuals which have not yet been cleared, or only partially so; and the prices at which this is to be had vary according to the quality of the land, its situation with regard to roads and markets, or the work which has been already done upon it. Large quantities of this description of lands are to be had in the north-western districts of Pennsylvania, at from two to four dollars per acre; many portions of it are fertile, situated on healthy mountain sides, and in a climate more nearly resembling that of Britain than is to be expected in the low though rich valleys of the western states, where the public lands are chiefly situated. In the other old-settled states there is not so much of this kind of unoccupied land; though, certainly, when it comes to be in America as it is here, where every inch of ground is wanted for raising food, an immense quantity of what is now despised, will, by the operations of draining, trenching, and reclaiming, be brought into productive cultivation. In these states, particularly New York, there is, however, always abundance of properties in the market, parts of which have been long farmed, and which have houses and offices erected on them, for extending the cultivation of their remaining acres. These are offered at various prices, according to their advantages; and to gentlemen who have skill and enterprise to introduce better and more careful modes of farming, they offer admirable capabilities. The profit which has been hitherto realised in America, has been by merely breaking up the woods and prairies into corn land in the roughest and most unskilful manner; but a new field of enterprise and wealth remains to those who shall introduce in the settled states better breeds of cattle and more scientific modes of agriculture. In general, the American farmers entirely neglect the use of manures; they very often shovel the refuse of their stable-yard into the nearest river; and one farmer is mentioned, who, rather than remove a dunghill which had gathered in his court, chose to build a new set of barns.* The national habits lead them continually to think of breaking up new land, and they always choose to do this rather than manure the old. They prefer, in short, taking their crop off a large field carelessly and unexpensively cultivated, to getting the same returns from a smaller piece of ground skilfully prepared. This is obviously a want of thrift as well as of science, and it is for this reason that we say that good farmers, with some capital, might take advantage of the half-improved lands which are on sale in the settled states,† and by buying them at the very moderate prices at which they are offered, enrich both themselves and the country, by the introduction of more business-like modes of farming. An attention to dairy produce, an improvement of the breeds of cattle, and the introduction of kinds which would produce fat of better quality, and with less expense or trouble than the kinds now known, would be of essential benefit.

The prices at which cultivated and half-reclaimed lands are offered in the district of Genessee (a fertile one), are from twenty to forty dollars per Mr Fergusson mentions several farms which he sale: one near Geneva was of 250 acres, "consist good loam, and some indifferent clay, well watere without any mill power. The wheat and India were excellent; the hedges thriving and in good with a double rail fence; the mansion-house and were very respectable. The price asked was 25 per acre, or L.1406, 5s. for the whole farm."

Mr Fergusson mentions the prices at which other farms were offered; we subjoin an abstract notices:—

"1. Captain Davenport's farm, on the east b the Hudson. It contains 350 acres, 100 of whi in wood: the soil is partly clay, partly sandy loa a large portion is a rich holm on the river side, finest quality. The price demanded is L.7, 10 acre, and it was sold at somewhat more than th soon after. The return might reasonably be ex to reach L.112, 10s. *clear of expenses*, from the fa and L.70 from the profit on a sheep stock on the portion of the farm; in whole L.182, 10s. The given was L.2000, and L.1000 more was requi building, fences, and drains—in all, L.3000; for there is a return of L.180. An industrious Scots f in Mr Fergusson's opinion, would not fail to L.200, clear of all the expenses of subsistence, &

2. Next to this farm was that of Mr Knickert containing 275 acres. There is a fine holm c farm, and the upland seemed fully better than It was let in shares last year, and the owner re L.63. The price asked was L.4 per acre, or L and L.200 more would be requisite for houses, &c. There was no more timber than seemed re for the use of the estate.

3. Mr Cherney's farm, 106 acres, with wood su for the use of the property—about 40 acres o fine holm, capable of yielding, I was assured, fo fifty bushels of oats, or other grain in proportion farm could be had for L.530, and would certain turn L.45 or L.50 clear.

4. Mr Vely's farm, 113 acres; 40 acres of superior holm; the upland good; with a strea ning through it. The houses appeared to be new. farm could be had for L.400, and the return co be less than from L.35 to L.40, clear of all char

5. A farm of 300 acres, occupied by Colonel at a rent of 300 dollars (L.67, 10s.) The soil i loam; nine parts of it are clay: a new dwelling- and good barn, with a valuable wood lot. It mi bought for L.1500.

The whole of these properties were evidently s tible of great improvement, though in foul and ba dition. The local situation is good, the Champlain passing within half a mile, though separated river. The roads are tolerable."

The account given of these properties by an i gent observer and agriculturist, will serve to c an idea of the prices of land, and the returns capital and industry employed in American agricu In all cases we believe it to have been well p that no person should buy more land, however ch offered, than he can immediately cultivate with a tage. The capital expended in buying super ground is completely locked up from use; and th cumstance, in a country where every disposable can be employed with certain profit, is a downrig pitiable loss. There are some persons, indeed, w has been already mentioned, speculate in land, l large quantities in order to sell it again, as it be more valuable by the increase of population; bu adventurers require to have well studied the n advantages of the district, and it is not a specu for emigrants.

To conclude, then, on this subject: Land in ne tricts, chiefly in the western states, may be had dollar and a quarter per acre; in places partially s unreclaimed land fetches from two to four dolla

* [illegible] Mr C[illegible], while residing on Long [illegible] this remark. His mode of cultivat[illegible] turnips, and other green crops; his [illegible] his sheltering of poultry [illegible] were much esteemed in America.

very favourable situations, perhaps a little more. Ground partially opened, and cleared of trees, is offered at all manner of prices, according to the labour bestowed on it, from four dollars to forty.

RENTING LAND.

There is little of what is called renting land in any part of the States; but where there is, the produce is generally divided into certain proportions between the owner and tenant. Sometimes each receives an equal share; sometimes the owner gets a third, according to the improvements on the land, and its quality; sometimes tenants take land "*on shares*," with the landlord, on condition that he furnishes them with seed-corn and fire-wood; and then he receives one-half of the crop. In the western country of Illinois, &c., it is not uncommon for the owner to give a man "team, tools, and board, besides one-third of the crop," for labouring a farm. Mr Pickering mentions that, in the neighbourhood of Baltimore, he was asked a rent of 18s. per acre for a lot of fifty acres, only half cleared; for another lot of very rich land, the rent asked was twelve dollars, or L.2, 14s. per acre.*

These lands had the recommendation of being situated near the markets of Baltimore; and it must be recollected also, in explanation of the high sums demanded, that the rent of land in America by no means bears the same proportion to its price as it does in England. With us, it brings twenty-five years' purchase of the rent. In America, it is freely sold at sixteen and seventeen years' purchase. This must be owing to the many profitable ways in which ready money can be employed in that country.

CHOICE OF LAND FOR SETTLING, WITH RESPECT TO HEALTH AND NEIGHBOURHOOD.

It is of the greatest consequence that the land which is selected be in a healthy situation, in whatever district it be chosen; and for ascertaining this, the emigrant must examine the spot himself. Let him trust the report of no other person; land dealers and others naturally commend tracts of ground which they have an interest to sell. The people of the neighbourhood are also to be distrusted, because they are all anxious to have settlers near them, from the additional value an increasing population gives to their property. There can, however, be little difficulty in making the choice. In the first place, the neighbourhood of all marshes is to be avoided, as well as of rivers, which, from their sluggish course and low banks, appear to overflow and stagnate in time of floods. Such situations are almost always liable to agues and fevers. The same may be said of low moist prairies (meadows), whose great fertility should never tempt any settler from this country to establish himself in them. An elevated spot, where the air circulates freely from all points of the compass, is most desirable. If circumstances should induce the settler to fix himself near any of the great rivers, it is asserted that a residence chosen as near as convenient to the margin of the stream will be more healthy than those situated a few hundred yards' distance, in what is called the "interior of the bottom." Along the Mississippi and Missouri, the banks are generally higher than the ground a little distance inward; and from the porous nature of the soil, this interior land absorbs moisture from the river, and remains always damp. So much is this the case with regard to the Missouri, that all the waters which it receives from its tributaries do not increase the stream, which is, therefore, as large 1000 miles from its mouth as it is where it falls into the Mississippi, after having received more than a hundred rivers in its course. This circumstance is attributed chiefly to the water being absorbed by the porous soil, whence it is partially evaporated in the surrounding air. This peculiarity renders the immediate vicinity of the rivers (except where they have a rocky channel) unfavourable to the health of persons lately arrived in the country, and whose constitutions have not been yet accustomed to the climate and atmosphere.

To emigrants from Britain, we would say, that the country of Michigan and the Highlands of Pennsylvania are likely to be least injurious to their constitutions, and that more caution is required in selecting a situation in Ohio, Indiana, and Illinois—the whole western country indeed—than in the former places. That country, from the number of years it has now been settled, however, has been thoroughly explored, and all its healthy and unhealthy situations ascertained; so that a settler will seldom be at a loss, in the neighbouring towns, to find some clue by which to guide himself.

In whatever place a settlement be chosen, it is of the utmost consequence that the *house* be on a dry and airy spot, and that it have a spring, or clear running stream of good water, close by, for household purposes: some, to secure this object, pitch on the banks of a pool or small lake as an eligible situation, which is the worst place possible, both because the water is often stagnant and unwholesome, from the dead leaves and vegetables lying in it, and because the effluvia from such water is apt to generate disease in those who are constantly near it. The floor of the house should, if possible, be laid with some hard dry substance; and a little fire should be kept in the evenings, even when the weather hardly seems to require it, because this serves to maintain a wholesome circulation of air, and to dry more quickly the green logs of which settlers' houses are first constructed. With regard to clothing, it is of consequence that those who enter upon this new life should make themselves somewhat comfortable in this respect; and though they must for a time submit to hardships, by no means to imitate the savage affectation of many of their neighbours, who think that, as they are in the woods, they ought to take a pride in living like Indians. These people often neglect all cleanliness and comfort, both in their persons and dwellings, and are vain of telling how much they expose themselves to the weather, both in sun and dew, and how well they have stood it for years. Let none of these vain-glorious boastings have any influence with the new settler: he ought, in every point, to maintain habits as little removed from his former way of life as is consistent with his situation; keep his clothes and house as snug and comfortable as he finds it possible at the present time to make them; and expose himself neither to the weather nor fatigue, except where there is some useful purpose to be gained by it; never at least to do so for the mere sake of bragadocio, or to imitate the ostentatious hardiness of some of his neighbours. He will find the Scots proverb, "hooly and fairly gangs far," as true in the backwoods of America as at home. Steady and cautious perseverance in clearing his lands and securing his harvests, with patience and good humour under such privations as are unavoidable, are chiefly essential to the success of the emigrant.

As a farther advice to settlers entering into the woods or new lands, we would say, that if two or three can go together, it assists them materially: a family with several stout sons has a very great advantage in this respect. A few acquaintances joining together, and taking a piece of land to divide among them, can assist one another in clearing it, or in getting in their harvest; and if any accident happens in one of their families, the good offices of the rest serve greatly to relieve its inconveniences. It may happen, for instance, that some of them gets a hurt, or is laid by for a week with sickness; and if this were to occur during harvest, or in seedtime, every thing would be lost, without the assistance of the rest of the company. If such partnerships cannot be formed before leaving

* The rents asked in America are certainly higher than might be expected from our ideas of the relative proportions of the price of land and its rents in this country. But as Mr Pickering, on whose authority we state the above facts, did not really take the land, and only inquired concerning it to gratify his curiosity, we are disposed to think a real bidder might have heard a lower price. In another place, Mr Pickering says he was asked three guineas per acre of rent—a sum quite incredible *to be paid*.

States who have not access to some stream in their neighbourhood for fishing, if they are fond of that pursuit, either for amusement, or as a means of providing food for their families. Every one has the privilege to avail himself of all the treasures of the waters, without let or hindrance; and they are worth taking advantage of. The shad and the salmon, of excellent kinds, abound in the rivers of the eastern states, and beautiful trout are taken in those of the north. Among the fish of the western waters are noticed the perch, one of which, the buffalo-perch, is a fine dish for the table, weighing from ten to thirty pounds. The pike, the perch, and other of the Illinois, and the rivers connected with it, are represented as excellent: a line called a trot-line, drawn across the mouth of the Illinois, with hooks at regular distances, took five hundred pounds in one night. The whole of the fish of the Mississippi are not, however, of equal quality for eating; the kinds which are chiefly the trout, the small yellow cat-fish, the [illegible] and the perch.

[illegible] privileges of the farmer, it would [illegible] over the game, which is abundant [illegible] rican woods, and which may sometimes [illegible]ment, sometimes an agreeable variety of [illegible] mallard, or common wild-duck, is found in [illegible]-water lake and river of the United States. [illegible]vass-back duck is an American species, altogether unknown in Europe; they are found in the rivers [illegible] and Delaware, but principally frequent the Chesapeake, where they feed on the roots [illegible]rass-like plant abundant in these streams: [illegible]out in shoals, but are exceedingly shy, and [illegible] be shot. The delicacy of their flesh, and the [illegible] they bring in towns, render them an object [illegible] pursuit to numbers. In general, however, [illegible]d to game of all kinds, though plentiful and [illegible], it is no object with the colonist, who does [illegible]e to waste his time in following it. Mr Fer[illegible]on of Woodhill met in Canada with a young Scotsman who had been a poacher in Scotland, but was now settled and thriving well on a farm of one hundred acres in his new country. Mr Fergusson said to him, "You will need neither certificate nor qualification here: what do you principally shoot?" "Indeed, sir," said he, "if you'll believe me, I scarce ever think about it, for there's nae body here seeks to hinder us." A herd of deer only two days before had wandered past him while at the plough, yet Walter felt no inclination to run for his rifle, though it stood loaded in the house.

WAGES OF LABOUR, AND COST OF LIVING.

The price of articles varies in different places, so that no general average can be stated either of wages or of the cost of living: both are different in different circumstances. But we have selected, from the best authorities, such lists, for several of the chief towns and districts, as will enable the reader to judge for himself.

Albany.—For Albany, on the river Hudson, we have, from good authority, the following statement:—

Wages.—Men for general farm work—Summer, L.2, 5s. per month; winter, L.1, 7s. per month. Harvest work, cradling wheat, 4s. 6d. per day. A cradle scythe is said to cut four acres a-day, and requires one man to bind to each cradler. Hay cutting, 2s. 7d. per day. Board found besides to all these. A steady active farm overseer or bailiff has about L.45 money wages, a capital house, a cow, and some other advantages. A man gets 8 guineas (or 21 dollars) for three weeks' work drying hops. Good cooks, 18s. to 27s. per month; chambermaids, 13s. 6d. to 18s. per month; washerwomen, 4s. per day; servant girls, 18s. to 24s. per month.

Provisions.—Wheat, 6s. 9d. per bushel; beef, per quarter, 18s. to 23s.; per lb., 2d. to 4d.; mutton, 1½d. to 2d.; veal, the same; pork, 22s. to 27s. per cwt.; butter, 5d. per lb.; cheese, 2d. to 4d. per lb.; eggs, 4d. to 5d. per dozen. Brandy (French), 4s. 6d. per gallon; gin, 3s. per ditto; whisky, 1s. to 1s. 1d. per ditto; excellent table beer, 4s. 6d. per barrel of 32 gallons. Firewood, 13s. 6d., country price; 22s. to 27s., to per cord of 128 cubic feet, delivered four feet cost 2s. per cord to cut to lengths required fo

"The American farmers," says Mr Fergus comfortably, and at a very moderate expense. and soap are generally manufactured from kit fuse. A good housewife assured me that the meat for her family, fifteen in number, did no *in whole*, 1s. per day (three meals), except w allowed them turkeys and other poultry, w reckoned the expense at 2s. 6d. The flour did not exceed 4s. 6d. per week. They have fr fresh and preserved, in the utmost profusion; cider barrel is always ready broached. A go articles of clothing are spun and woven at ho the geese are subjected to periodical contribu wards the bedding of the household, or the feat sold at a good price."

Baltimore.—Mr Pickering, who went to this look for a situation as overseer of a farm, mem following prices as current there:—

His own lodgings and board, at a respecta carpenter's (including washing and mending), per week.* In the markets, beef, 2d. to 3½d. the best cuts, 4½d.; pork from 2d. to 3½d. per sometimes lower; veal and mutton, by the 1s. 2d. to 2s. 3d.; good lamb, 4d. per lb. 1s. 2d. to 2s. 3d. each; fowls, 6½d. to 9d. each. (drumheads), 1d. to 2d. each; potatoes and 10d. to 14d. per bushel. Wild-ducks, 3½d. to 5 the canvass-back duck, a large bird, and est great delicacy, 13d. to 18d. each; partridges, 4 each; quails, 1d. to 2½d. each; hares and (small), from 6d. to 1s. each; shad (a fine fis herring, but ten times the weight), 13d. to 18d Apples, very fine, 13d. to 2s. 3d. per bushel peas, 1s. to 1s. 8d. a-peck.

Ship-carpenters' wages from 7s. to 9s. per da was higher than the usual rate, on account of demand for hands at the time. A young man apprentice to a shipwright, had 13s. 6d. per week for first year, and 22s. 6d. per week second board himself.

Philadelphia.—In the "Price Current" of P phia we find the following rates given on w articles:—Mess beef, per barrel of 196 lbs., 47s. 2d.; butter, per lb., 4½d. to 5d. (best quali cuit, best, per lb., 2d.; mould candles, per lb dipped candles, 4½d.; cheese, in casks, 3d. to 4d. 5½d. Brown shirting, 3d. to 4½d. per yard. superfine, per barrel of 196 lbs., 20s. 1d.; Indi meal, per 196 lbs., 15s. 1d.; hams, 5d. to 5½d. honey, per gallon, 2s. 1d.; loaf sugar, per lb., 8d.; brown sugar, 3½d. per lb.; brandy, per 7s. 2d.; Virginia tobacco, 1½d. per lb.; Cuba 5½d. per lb.; wine, Madeira, per gallon, 5s. 2d. to Port wine, per gallon, 4s. 6d. to 5s. 9d.

These are the wholesale prices; articles of p are furnished in the markets as follows:—The b from 3½d. to 6¾d. per lb., according to what pa animal is selected; fat mutton, of excellent quali chickens about 2s. 1d. a-pair; turkeys from 3s 7s. a-pair. Butter varies, according to the tim year, from 6½d. to 18¾d. per lb., averaging abo Superfine wheat-flour, 19s. 8d. per barrel of 1 kidney beans, 1s. 1½d. per peck; cherries (goo per lb.; good rye whisky, 1s. to 1s. 2d. per gallo ditto, less.

As to the prices of labour in Philadelphia, surrounding country, we find it stated, that a la man gets from 3s. 2d. to 4s. 6d. per day, in th and at farm-work, in the country, he receiv L.1, 16s. to L.2, 14s. per month, besides boa lodging. An attentive handy servant girl is

* The living was—a roast turkey once or twice a-week beefsteaks, ham, sausages, and a kind of pudding; pi fish, &c. A variety of the above was placed on the table meal, and generally three kinds of vegetables, with cof at breakfast and supper.

nther. In the steam-boat the fare is higher; ances is 145 miles: he took provisions with him hours, as did the rest of the passengers. From he took passage in the canal to Lockport, near rie, distance 300 miles—fare, a little more than ney per mile for himself and one trunk, paying t. for the other, which weighed 75 lbs. Passed ferry on the Niagara river, to Canada—charge, This was in the year 1826.

Fergusson of Woodhill travelled the same route New York to Albany, some years later (1831). arges of freight were then considerably lower: t in the cabin of the North America, a magnisteam-boat, and paid only 3s. fare for the whole iles, with a very moderate charge for meals—2s. 3d. for dinner, including brandy, whisky, and ds, placed on the tables at the discretion of the gers. He returned from Canada by the Erie to Rochester: the fare from Buffalo to Rochester, les, 15s. 9d., three capital meals included—the good, the cabins amply supplied with books and kets, and the tables with good cheer. Travelled ed coach from Geneva to Albany, 170 miles, 1s. 6d. No extra charges given to coachmen or persons.

Fergusson afterwards went from New York to ington, and found the charges as follows:—From York to Philadelphia, by Bordentown (where Bonaparte lived), by steam, with 30 miles of arriage, 18s., including breakfast and dinner: n the William Penn steam-boat from Philadelphia timore, 120 miles (going through the Delaware hesapeake Canal, 14 miles), fare 18s.—breakfast inner, both excellent, were charged 2s. 3d. each. Baltimore to Washington in the stage-coach, 30 fare 12s. 6d.; got a neat light coach, a pair of well-fed horses, and a black driver to go to Mount n (the former residence of General Washington), ance of about 12 miles—fare, 13s. 6d.

the account of travelling expenses, it must be d, that passengers may always carry their own ions when in steam-boats, or canal boats, and by eans reduce the amount very considerably.

ERS OF THE PEOPLE, AND THEIR CONDUCT TOWARDS STRANGERS.

have now presented a fair and impartial view United States of America, as regards their ility for the purposes of intending emigrants. e preceding information has been very carefully from every accessible source, and rendered as ete as possible, nothing remains to be mentioned can concern the interests of emigrants, unless few observations on the manners of the people have an intention of residing amongst.

w persons know or care about those little peces of speech or manner in which the people of county or district differ from those of another; r instance, in what the dialect of the natives of shire differs from those of London, or that of the of the south of England from the same class north of Scotland. These matters are of very importance to the comfort of a stranger going ide among them; but it is of some consequence m to know if the new people with whom he is to pass his life are kind and hospitable to those ome among them, or if they are jealous and inat in their manners, and disposed to repel the adss of strangers. There are many such people look new comers as intruders, and take every means ke them feel that the country they have come to gs to others. Is this the case with regard to ica? may be naturally asked by emigrants who of proceeding thither. On this subject we might l to the many invitations which are daily circulated e Americans and their friends, calling on all who stitute of employment and subsistence in Europe, ne freely to that country, where they are assured dial welcome and abundance. But this following

extracts from the journal of Mr Fergusson may show how our wealthy travellers are received there; and we shall then subjoin a similar specimen of what the poor are to expect.

"I could say much," says Mr Fergusson, "were it proper, of the hospitality of New York, and of the unostentatious kindness with which my letters of introduction were received. The style of living is elegant and comfortable, and the domestic circles which I had the pleasure of joining seemed truly unaffected and happy. The quiet, modest, and amiable tone of female society particularly pleased me."

We give a second extract from the same traveller. "I learned also, from a Scotsman in Mr Thorburn's employment, whose family had suffered heavily from sickness last winter, that flowers and parties by no means engross the sole attention of the ladies of New York. He assured me, that, within his own observation, it was quite wonderful what they continued to do, in visiting, clothing, and attending to the poor. This man left Glasgow in great destitution about a year ago. He is now in comfortable circumstances, and his family provided for; but the first fortnight which honest Saunders Lee spent in New York, a total stranger, without money or engagement, he described with a shudder, as '*perfectly awful.*'"

The following extract is from the letter of a female emigrant, whose husband had fallen sick on his arrival:—"We hired a room, and my husband bought a saw, and went sawing wood, and doing any thing; and we thought we should get through the winter pretty well; but after about three weeks, he was taken ill, and it proved to be a typhus fever. We had no parish to apply to for relief; but you would be astonished at the friends we have found; for people that were quite strangers have called to know *if the sick Englishman lived here;* one kind gentleman sent for a doctor, and another good old Methodist gave me leave to go to the grocers for any thing in his name; and others were equally kind. I never thought I should meet with such friends among strangers. My husband is now mending fast."

Mr Flint says—"To-day a vessel from Dumfries arrived; and a few minutes after she was moored, one of the brothers Messrs Robinson went aboard, making inquiries after the views and circumstances of the poorer classes of emigrants. He soon perceived one of them, pointed out where several others would find work, and gave advice to the rest. This is not a new or rare instance of benevolence on the part of these gentlemen."—"Every day numbers of European emigrants are to be seen in the streets [of Philadelphia]; I have never heard of another feeling than good wishes to them."

It is frequently mentioned, that difference of rank or of wealth is not so much thought of in America as in this country, and that the industrious labouring man stands more nearly on an equality with his employer than with us. The following extracts relate to this subject.

Extract of a letter from a labourer:—"A person may not think of coming here without working, and may despise drunkards; but if a person keeps steady, is respected much more than in England; he is admitted at table with the master."

The following extract is illustrative of American manners in various respects. It is from Mr Stuart:—"When they meet us in the street, they, whether accosted by us or not, touch the brim of their hats, and very civilly enter into a talk with them, and will [illegible] which we decline to avail ourselves of, as we have invitations, and to dine at work-time. There are few more striking points of difference between this country and Britain, than in the [illegible] with which people [illegible] on the public roads. [illegible] a gentleman walking [illegible] proves the easy circumstances of the mass of the people, as well as the [illegible] pay for a conveyance and spend less time, than and spend more."—"We have not hitherto," in another place, "seen any thing like a poor house, or a beggar, or any one who did not seem clothed and well fed."

Such are some of the traits of character of the bitants of North America, who, although speaking English language, and living under institutions English in their character, differ, as may be seen in several respects in their manners from the p this country. They do not lay claim to that ar and polish which distinguishes what is called society" in Great Britain; they are more do and frank in their behaviour, less ceremonious, in every way a more independent people in their t and actions than the generality of English and From all that we can understand of their ch they seem to possess less of the quality which p "cringing" than any people on the surface of th It may be conceived, from the extraordinary of classes of persons from most European co and the wide field offered for adventure and ent that the Americans have little of that staidness position and subdued tone of mind which are teristic of the British nation. Society, in the p settled districts, is therefore still in a loose co and emigrants will require to be more alert in to their interests, and much more on their guard deception, than in this old-established country deeply to be regretted, that, for a number o there has been a class of writers in Great and a few travellers, whose deeply-rooted objec been to vilify the American nation in the gross hold up not only their institutions and usages, that belongs to the country, whether in nature as fit subjects of ridicule and contempt. The m calumnies which have been industriously circul these splenetic writers, need not in the smallest produce hesitation among emigrants in refer settling in the United States. The citizens of th American Union are essentially British in thei and character. Their other peculiarities have a arisen from the fortunate circumstances unde they are placed; and in which peculiarities w equally partake, had we fewer public burdens causes to be careworn, as well as a greater s the profitable exercise of our industry. In co Canada with the States, every intelligent t allows, that the citizens of the Union are i more active than the subjects of Great Britain. the colonial territories, all public works, and the settlements, proceed slowly, the system to be rather inert; while on the States' side boundary, every species of work proceeds w most astonishing rapidity—canals being cut, t formed, and towns built, in an inconceivab space of time. As Upper Canada has nearly t natural advantages as the States, and as the p may be presumed, are as well educated and ready intelligent, it would seem that the true the difference we speedily is in the mode of co public affairs. It may be conceded, that the p are as well managed as they could possibly be must also be allowed, that it is not in the n things that a country, with its seat of gov three thousand miles distant, can be so advant conducted as in a closer country, where the gov is at hand, on the spot, but consists; the peop serve. It is not, however, our object here to d comparison between the political condition of t ne and States. Both have free institutions, a possess those capabilities which can yield co settlers. The honest, the industrious, and the prising, will do well in either, and will comm spect and ascendancy wherever they may fi place of settlement.

ED SERIES. PRICE 1½d.

AUSTRALIA.

th beyond the 145th meridian, and on the south be-
d the 140th, and found "that the country preserved,
ar as he was able to see from some hills, the same
orm appearance of an immense level plain. This
ensive country resembles as little the plains of South
erica, covered with abundant grass, as the African
ara, with its moving sands: it seems to approach
haracter to the wide steppes which surround the
e of Aral, and extend to the Caspian Sea and the
l Mountains. But we are inclined to think that
y are somewhat better adapted to sustain inhabi-
s than the steppes of Asia. These plains of Australia
, in many parts, extremely level; in others, they are
ntly undulating; and here and there, but at great
ances, sometimes of more than a hundred miles, a
dy eminence rises, which hardly deserves to be called
ll: the loftiest of these eminences are not above
foot higher than the plain on which they stand.
ll over this extent of country the soil presents only
varieties: it is either a red sandy loam or a white
rse sand. In some places it is entirely destitute of
etation, in others it nourishes only salsolaceous
nts, without a blade of grass between them. Others,
in, are covered with polygonum, a gloomy and leaf-
bramble; and in a few tracts patches of ground are
overed, which appear to be moist, and in which the
stemma is abundant. Such patches probably form
ksands in the rainy season. Those parts of the
ns which seem to have the best soil produce stunted
-trees and cypresses. Large tracts of country are
ered with shells and the claws of crayfish; and this
, although an alluvial deposit, is superficially sandy.
y bear the appearance not only of being frequently
ndated, but also of the floods having subsided upon
m. On their surface no accumulation of rubbish is
erved, so as to indicate a rush of waters to any one
nt; but numerous minor channels are traced, which
ently distribute the floods equally and generally
r every part of the area which is subject to them.
'My impression,' says Captain Sturt, 'when travelling
country to the west and north-west of the marshes
he Macquarrie, was, that I was traversing a country
comparatively recent formation. The sandy nature
he soil, the great want of vegetable decay, the sal-
aceous character of the plants, the appearance of its
ated hills and flooded tracts, and its trifling elevation
ve the sea, severally contributed to strengthen these
ressions on my mind.'"*
he conjecture of Captain Sturt, that Australia is of
ore recent formation than the rest of the globe, is
no means singular, but how far it is correct it is
e unnecessary to inquire. It is at least remarkable,
nature has, in several instances, put on very diffe-
t forms in Australia from what are customary else-
re. Among the animal tribes, the chief are of the

* Penny Cyclopædia.

pouched kind, and move forward by springing. The kangaroo is the principal animal of this description, and there are different kinds of it; some are from four to five feet in height, when sitting on their hind legs. They will, in some cases, leap twenty feet at a single bound, by which odd species of movement they are able to outstrip a horse at full gallop. This interesting and pacific class of animals is fast diminishing in numbers; they are now seldom seen in the settled parts of the country. Opossums are numerous. There is an animal half-bird half-beast, or possessing the bill and feet of a duck, and the body of a mole or rat (ornithorhyncus paradoxus). Wild savage animals are unknown, the native dog excepted, which has been pretty well hunted in some quarters. Of birds there are some singular varieties, both large and small. There are, in particular, a great variety of parrots, parroquets, and cockatoos, all with exceedingly beautiful plumage—green, red, purple, and white. The doves are equally splendid in their feathery coverings. There are several kinds of native bees, "which are without stings, and produce a great deal of delicious honey."—(*Martin.*) Of snakes there are several varieties, some of them poisonous. Musquitoes prevail in the uncleared districts, as they do in all warm uncultivated regions where there are marshes and trees to harbour them; but we do not see it any where mentioned that they form that horrid nuisance which they are in almost every part of North America. In some places, fleas are described as forming a serious nuisance. The rivers abound with fish, some with cod of a large size; and of aquatic birds the usual kinds are seen, including swans of a dark colour. Shrimps, mussels, and oysters, are plentiful; the oysters, though small, are of a very superior quality, and abound on some parts of the coast to an extent quite unprecedented in any other quarter of the globe. The seal and whale fishery on the coasts of Australia offer boundless scope for profitable adventure to those acquainted with this branch of industry, and who have capital to risk.

The mineral riches of Australia are also of great amount. "Coal and iron, the most valuable of minerals, are met with in inexhaustible abundance, the latter being not infrequently found in the state of native iron in large detached masses on the surface of the ground. Limestone is still more abundant, and in some parts of the territory, as in Argyle county, New South Wales, it passes into marble, of which beautiful specimens have already been cut and polished by a skilful artisan from London, now established in Sydney."—(*Lang.*) The colony also possesses clay fit for pottery. A manufactory of brown and glazed earthenware, of the best quality, has lately been commenced on a large scale at Irrawang, near the confluence of the Rivers William and Hunter, by that enterprising and scientific settler Mr King, the well-known discoverer of the superior quality of Sydney sand for the manufacture of glass.

Vast as are the latent resources of Australia with respect to its fruitage, mining, and fisheries, it is not to these departments of industry that the country at present looks for its advancement. Its grand resource consists in an "illimitable extent of pasture-land, which it presents to the sheep-farmer or the proprietor of cattle in every direction."—(*Lang.*) No country on the face of the earth seems to be so admirably adapted for the feeding of sheep and produce of fine wool. America, as is well known, is not a sheep-feeding or wool-growing country. In Canada and other northern parts, sheep require to be housed and fed by artificial means for several long winter months; while on the fine prairies of the States, the sheep which are left at large throughout the year do not yield wool of a valuable quality. Australia, on the other hand, resembles Spain in its qualities for pasturage in all seasons; and its climate produces equally fine, if not superior wool. At the present moment, Australian wool enjoys the highest reputation in England and America—it takes the lead in the market—and so readily and so profitably is it disposed of, that the cost of transport of sixteen thousand miles goes almost for nothing in the grower's calculation of profits.

Most of those beautiful and soft woollen fabrics go by the names of Indianas, Merinos, and Cl are in so great request by ladies, in the shop haberdashers, are chi manufactured from Australian wool; is obvious, from the taste and dex so articles, whilst suited to our , (barring fiscal the production and sale of this species of wool become one of the first trades connected wit commerce.

The aborigines or natives of New South W now very inconsiderable in numbers. They nual wandering life of savages, roaming th interior in small tribes, each claiming quarters a respective territory. They are jet plexion, and in general tall and thin in s, with large heads, large lips, and wide and are altogether the reverse of beautiful, to our ideas of that quality. They have be dered, although the opinion is not complete out by experience, as amongst the lowest of savages in the scale of intellect. There is less mechanical genius amongst them—few vances to improve the original condition of are to be found amongst the natives of any ot ter of the globe. Their only arms are a rude rather pointed pole, which, however, they th great force and precision; and a short club, themselves a *waddie*. Their huts are of the description, and they wear no sort of covering on their bodies. All attempts to civilise them induce them to abandon their wandering h hitherto been nearly ineffectual; and with th tion of a few in the neighbourhood of Sydney, other of the colonial towns, whom this contin in some degree, forced into a half-domestica they still wander in roving tribes throughout rior. From the latest accounts, it does not ap the white settlers are now suffering much fr miserable beings; indeed, it seems that any po command their good will by the slightest efforts ness and conciliation.

The climate of Australia, confining ourselves to the settled portion of the country, although considerably in different districts, is altogether agreeable and salubrious. According to Mr ham, who was a surgeon in the colony of N Wales, exposure produces no bad effect, from ness of the atmosphere; and it has been recom to consumptive patients. The summer comm December and extends to February, durin period the heat is considerable. Dr Lang st the thermometer seldom rises above 75° in Sy cept when the hot winds blow from the west. writer mentions having walked two miles t with the thermometer at 146° in the sun and 8 shade, yet felt no inconvenience, the air being pure. In the lower districts the air is tempe cool and delightful sea-breeze, which blows ste regularly throughout the day, and is succeeded by an equally steady and grateful breeze from The average temperature at Sydney during 55°, and there is only one instance on record having fallen in the town, which was on the 1 1836. In the higher districts, of course, th greater; the thermometer at Paramatta someti ing so low as 27°, and in the district of Bathu lies for a short time in winter.

A peculiarity in the climate of Australia is valence of hot winds during the summer. Th from the north-west, and resemble a strong c air from a heated furnace, raising the therm 100° in the shade and 125° when exposed to fluence. They seldom occur more than fou times every summer, and last only a few d has been supposed that these winds derive t treme heat from passing over a great extent of heated country, which deprives them of all m Breton, in his Tour in New South Wales, s

unpromising appearance of the shores of New
th Wales is not removed upon landing. For five or
miles inwardly, the land continues barren and rocky,
senting few other signs of vegetation besides some
ly scattered stunted shrubs and dwarf underwood.
this distance inward a marked change begins to take
e; the soil improves, and begins now to be encum-
ed with tall and stately trees, which soon again
ken into a dense but magnificent forest, indicating,
ed, a more luxuriant soil than that passed, but
rely less discouraging to the settler. Advancing
ards, however, from six to nine miles farther, an-
r change takes place. You have cleared the forest,
the promised land lies before you, improving with
ry step you advance; now presenting an endless
iety of hill and dale, covered with the most luxu-
nt vegetation; now extensive plains, resembling the
st parks in England—a resemblance which is made
more striking from their being similarly interspersed
h magnificent trees, just numerous enough to add
uty to the land without encumbering it.
uch is, with few exceptions, the whole of the eastern
st of Australia. The colony is, or was lately, divided
the following counties:—Ayr, Argyle, Bathurst,
gle, Brisbane, Camden, Cook, Cumberland, Cam-
lge, Durham, Georgiana, Gloster, Hunter, King,
erpool, Macquarrie, Murray, Northumberland,
lip, Roxburgh, St Vincent, Wellington, Westmore-
d, and Melbourne. To these additions are constantly
ing place, and we therefore do not pledge ourselves
the accuracy of the list.

lgr.—This county is remarkable for the vast pro-
tion of high, rocky, barren, and mountainous land
ch it presents; it is also, in general, so thickly tim-
ed as to give the greater part of it the appearance
me immense forest. The quantity of land capable of
tivation in this district, is therefore comparatively
all; and though there are some good tracts occa-
ally to be met with, it is not, on the whole, by any
ans a desirable quarter of the colony to settle in.
climate, too, has been found to be highly unfavour-
le to wheat; and the hills are bleak, poor, and brushy,
not well adapted for grazing. Port Macquarrie,
of the penal settlements of the colony, is in this
nty.

Durham.—There is but a small portion of this county
ated, as it is called, that is, possessed by settlers; and
general appearance, so far as it has been explored,
the greater number of the other districts, is exceed-
ly varied, often presenting the most beautiful scenery,
equally often the reverse: on the whole, it does not
m to be by any means rich in suitable localities for
agricultural emigrant. Notwithstanding, however,
unfavourable character when generally spoken
it contains some of the finest lands in New South
les; these are to be found in the neighbourhood of
Hunter and Patterson rivers, on the south and
th-east side of the county, as laid down in the maps.
e fertile valleys and soft green undulating hills of
s part of the country, are spoken of rapturously by
who have seen them; they are, however, of course,
already located, and not an acre worth taking can
e be had, except by purchase from the present pro-
etors. In this district is situated the large and com-
dious harbour of Port Stephen, and the township of
itland, the capital of the district. Maitland is one
the most considerable towns in the colony, and has
w daily steam communication with Sydney. The next
trict, pursuing the line of coast, is

Northumberland—lying between Port Hunter and
oken Bay, a distance of about fifty-five miles, and ex-
ding inland about eighty miles. This county possesses
usual proportions of grazing land, and barren and
tile tracts. The best lands, though there are many
ner beautiful and desirable localities, are to be found
the neighbourhood of Patterson River, which divides
from the county of Durham. Within this county is
nated the town of Newcastle, so called from the abund-
supply of coal which it affords; the whole surround-

ing country, as well as a line of coast extending from sixty to seventy miles on either side of it, presenting evidence of its abounding with that valuable mineral. The coal is of a very good quality, though rather small, and makes a brisk fire. The Australian Agricultural Company have a lease of the mines from government, and they supply coal at the pit for 8s. a-ton to the dealers, who supply Sydney and other places at from 20s. to 30s. per ton, this great increase to the price being caused by the high rate of wages. The company have a powerful engine to work the coal and load vessels.

Cumberland.—Following out the line of coast, as originally proposed, we now come to the county of Cumberland, which has a coast line, stretching southward, of about fifty-six miles, namely, from Broken Bay to Coal Cliffs, about eighteen miles south of Port Hacking, and running inland about forty miles. This county, though one of the smallest, and in point of fertility of soil one of the worst in New South Wales, is nevertheless the most important of the whole, from its containing the principal towns in the colony, and amongst these Sydney, the capital. In this county, also, is situated the celebrated Botany Bay. The towns and ports in this district are Sydney the capital, Paramatta, Windsor, Liverpool, Campbeltown, and Darling Harbour. By a reference to the map, it will be observed that the coast here is opened up by spacious inlets of the sea, all of which form excellent harbours; into the head of one of these harbours flows the Hawkesbury River, whose banks present a stretch of fine alluvial lands, to the extent of a few thousand acres.

Sydney is situated about seven miles inwards from the head of Port Jackson, which is considered to be one of the finest natural harbours in the world. It is built upon two necks of land, with an inlet between called Sydney Cove, possessing a depth of water which enables vessels of the greatest burden to come close to the land. Half a century ago, the ground on which Sydney stands was a barren desolate wild, covered with wood, and tenanted only by savages and the kangaroo. In the year 1800, its population, consisting of free settlers and convicts, amounted to about 4000, and now it is reckoned to be upwards of 30,000. Sydney is in general a handsomely built town, and here are to be found more than all the conveniencies and luxuries of a British town of the same extent—regular and handsome markets, public seminaries, banks, flour-mills, warehouses, hotels, distilleries, breweries, steam-engines, stage-coaches for different parts of the colony, five newspapers—the Sydney Herald, the Sydney Monitor, the Sydney Gazette, the Australian, and the Colonist, besides the government Gazette, equally respectably-looking periodicals with any published in this country. Being the seat of government, here centres the colonial business; and the shipping to and from England and other parts of the world is on an extensive scale.

The wharfs and warehouses in Sydney are of surprising extent, and the fine secure harbour in front, so advantageously adapted for general traffic, as well as the reception of vessels employed in the sperm-whale fishery of the southern ocean, is a grand feature in the scene. From all we can learn of Sydney, it appears that the industry and enterprise of its inhabitants, acting on the great resources around them for inland and external trade, promise to raise this chosen seat of population to a high pitch of prosperity; and we may expect that in a few years Sydney will be by far the most important British city in the colonies. The environs of the town are said to be very charming, and include a botanic garden, laid out with handsome walks and rides.

Next to Sydney in importance, though much inferior to it, is Paramatta, situated at the head of the narrow inlet of the sea in which Port Jackson terminates above Sydney. Between the latter place and the former, a distance of about sixteen miles, there is frequent and regular communication both by land and water, two coaches, one morning and evening, and two passage-boats, daily plying between the two places, the fare of the former 4s. inside and 2s. outside. N exceed the beauty of the scenery which pr on all sides as you proceed to Paramatta by sea generally smooth as glass, or but gently a slight breeze; innumerable little promo vered with wood to the water's edge, stre the sea, and forming a corresponding numb tiful little bays and inlets, in endless suc variety. Paramatta contains upwards of bitants. The greater part of the houses he of brick or white freestone, and being for th unconnected with each other, cover a gre of ground altogether than its population wo warrant. The situation of Paramatta is delightful. It lies in a spacious hollow, co the richest verdure, and surrounded by hills rate height. Here, too, are churches, hote seminaries, &c., and all the other appendag siderable country town, with a military a barracks, jail, government house, and the tory, an establishment for the reception of female convicts. Many of the private ho elegant construction, with parks and garden the place altogether thus forming rather an of cottages than a town: the streets, howe gularly laid out, running north and south west.

Pursuing an inland course for about twenty the traveller next arrives at Windsor, c population of about 2000. From Parama little town a coach runs three times a-week. which, in the description of its buildings, m bles Paramatta, is built upon a hill close by Hawkesbury, which forms the north and western boundary of the county, and whi circuitous route of about 140 miles, disch into Broken Bay. Windsor also contains a government house, with extensive gardens churches, a jail, court-house, military and c racks, taverns, inns, shops, &c. The lands in bourhood of Windsor are exceedingly ferti advantage is more than counterbalanced by i liability to inundation from the Hawkesbu sequence of its vicinity to the Blue Mounta has been known to rise to the almost incred of 93 feet above its ordinary level. Inunda and 30 feet are of frequent occurrence, and quences to settlers within its reach are ofte always ruinous to their settlements. The which is built on an eminence of about 100 the level of the river, has hitherto escaped mendous overflowings; but as its elevation highest known floods is only a few feet, it considered as free from danger. Next to Win portance is Liverpool, at the distance of abo or twenty miles from Sydney, in a south-west Between these two places a stage-coach ru times a-week. Liverpool is situated on th George's River, which discharges itself in Bay. It possesses a church, two or three stores, court-house, jail, and the usual accom of a town in New South Wales—a convict ar barracks. The soil around Liverpool is of different quality; but as the town occupies situation between Sydney and some fertile d the counties south and west of it, it is, notwith a place of considerable bustle and of rising im George's River, on which it is situated, an about half the size of the Hawkesbury, is nav boats of about twenty tons burden as high town. Recurring again to the coast line, w the county of

Camden—extending south from Coal Cliff Haven, a distance of from thirty-five to forty stretching interiorly north about sixty miles, average breadth of about twenty miles. The yet any towns in this county. It possesses, ho average quantity of fertile land, but is greatly d water; the very limited supply which it posses

rom branches of the Cow Pasture and other
is defect operates, as might be expected,
inst the prosperity of the district, since,
t important element, its fertile plains can
mptation for the settler. Nor is there

neight (the highest not much exceeding 3000
they are so numerous, extensive, and withal
that but a very small portion of cultivable
. It is not, however, without some fertile
some excellent grazing districts. Amongst
these is an extensive flat called Emu Plains;
neral character of the country is highly un-
to the agriculturist. There being little more
of particular notice in this county, we proceed
ining county of

a—situated behind the Blue Mountains, and
n the north and east by the counties of West-
and Roxburgh, and thence stretching south
nteriorly, but without any definite limits being
d to it in that direction. This county presents
ar and varied surface. It is, however, com-
lightly timbered, and generally easily acces-
, although particularly adapted for grazing, it
nly a small portion for the plough, and that
merely of occasional patches on the banks
nd streams. As a grazing district, however,
nferior to the best in the colony, and, in this
iew, is an exceedingly desirable place for the

gh is separated from the sea by the counties
mberland and Durham, and lies beyond the
ntains. It contains a large proportion of hilly
n country, but possesses some tracts of good
d, and is well adapted for grazing.

Bathurst.—This county at one time formed a portion of Roxburgh. It consists of extensive plains of remarkable beauty and fertility, and contains many thousand acres of the finest pasturage. These are now covered with the flocks and herds of settlers to an immense amount, this territory alone furnishing the greater proportion of the whole quantity of wool exported from the colony. It has also acquired great reputation for its dairy produce, and is considered, with regard to its cheese, as the Cheshire of New South Wales. Settlers here, however, labour under the same disadvantage with all those in the interior districts, namely, the being far distant from any market. This, however, materially affects the agriculturist only, and not the grazier, whose property can transfer itself. The rich territory of Bathurst Plains was discovered only a few years since, and was then considered, as it still is, a discovery of the highest importance to the colony. Nearly the whole of the available lands in the counties next the sea, occupying the space between the barren range of mountains and the coast, having been already located, or in the possession of settlers, there was none left for the thousands that were yearly arriving in the colony. On the discovery of these fertile plains, therefore, the superabundant emigrant population, which had been pent up, as it were, on the narrow strip between the mountains and the sea, left that territory, and, crossing the mountains with their flocks and herds, poured down upon this new land of promise, spreading themselves and their flocks far and wide over its rich pastures.

The climate at Bathurst, from its great height above the level of the sea (about 2000 feet), is considerably colder than in the eastern districts near the coast, and on this account, none of the tropical productions, which thrive so well in the latter, can be raised there to any perfection. In the midst of these fine lands is a thriving town of the same name, namely, Bathurst Town. Here there are several institutions, bespeaking the wealth and intelligence of the surrounding settlers. Amongst these are an academy, literary society, and public library. Proceeding still northwards, we arrive at the county of

Cambridge, which is separated from the sea by the county of Ayr. The land is in general good for grazing, but it is said sometimes to be inundated with water from the mountains. It formerly contained some valuable flat land, which now forms part of the county of

Liverpool.—This county contains a tract of valuable land called Liverpool Plains, lying behind a range of mountains which run east and west. Although of a very inferior description of land to Bathurst Plains, these are, notwithstanding, well adapted for grazing cattle and horses; but from their being subject to inundation in the rainy season, the best portion of them being under water during that period, they are neither adapted for agricultural purposes nor for the rearing of sheep. The Liverpool Plains extend about forty miles in every direction. There are few settlements in this county besides those on the plains just named, although it possesses some very eligible lands; but they are remote, and of limited extent.

COLONIAL GOVERNMENT.—SOCIETY.—TRADE, &c.

The government of New South Wales is conducted by a governor and a legislative and executive council: both of the two last, as well as the governor, are appointed by the ministry at home. The legislative council is composed principally of persons holding official situations, and these chiefly residing in the government towns. The executive council, again, is composed of persons filling the highest government appointments. There are, besides, a class of functionaries called police magistrates, distributed throughout the colony, and who take especial cognisance of offences committed by convicts, whom they have a power to punish by flogging or condemning to work in irons.

Sydney is the chief seat of the colonial government, comprehending the supreme court, and the heads of all the civil and military establishments of the country.

Being a colony of Great Britain, the laws by which New South Wales is governed are the same in their leading features with those of England, differing only in instances where such difference was found necessary to adapt them to the peculiarities of the country. The colonies of South and Western Australia have governors appointed by the government at home. They have also councils much the same as New South Wales.

The external and domestic trade of Australia has scarcely yet emerged from a state of infancy; but it is fast gaining strength; and if no unforeseen circumstances should arise to check its prosperity, Australia will one day become, if it is not so even now, by far the most important of all the British settlements abroad. Its leading export articles are wool, and seal and whale oils; a great part of the latter is of that valuable kind called sperm-oil, produced by a description of whale found in the South Seas only, and which generally brings double the price of the common whale-oil. In the article of oil, which has only very lately become an object of serious consideration to the colonists, the improvement has been remarkably rapid, there being now upwards of 40 vessels, averaging a tonnage of nearly 10,000, belonging to and sailing out of Port Jackson alone, exclusively engaged in the whale fishing. A striking evidence of the increasing prosperity of the colony, is the circumstance of its having, in four years, in some instances nearly, and in others more than doubled, the amount of its property in cattle and sheep, and the extent of its cultivated land.

The revenue of New South Wales had advanced in 1837 to L.226,900, 3s. 10d., independently of the revenue from the sale of land, which was upwards of L.127,000. The principal source of the colonial revenue is the duties exigible on liquors, and for licenses to dealers—a fact in itself distressing, for it argues a state of debasing intemperance. The land-revenue is a most important item; but from all we can learn, it has latterly been devoted to a liquidation of expenses incurred for jails and police, instead of paying for the import of free labourers. There is, therefore, on this point, great room for amendment; and such is the increasing attention paid to the subject by the colonists, that it may be expected to be arranged on a satisfactory footing.

We need not particularise the great and miscellaneous import and export trade of the colony, but confine ourselves to a few leading facts as an evidence of general prosperity. The imports, which amounted to L.280,000 in 1826, had increased to L.1,251,969 in 1839; whilst the exports from the colony, including the produce of the fisheries, had increased from L.106,600 in the former year, to L.948,776 in the latter. In 1824, the exports of wool amounted to 275,560 lbs.; in 1837, they were 4,606,915 lbs. In the Savings' Bank of New South Wales, the deposits increased from L.24,469 in December 1835 to L.127,000 in August 1840. The interest paid for deposited money in the ordinary colonial banks is, we believe, at the rate of from 6 to 8 per cent.; and at these banks bills on London will be discounted on favourable terms to emigrants bringing money in this form. Parties emigrating should exchange their cash for bills at respectable and old-established banks before leaving home, this being in every respect the safest mode of transfer. The currency of all the colonies is reckoned in pounds, shillings, and pence, as in England.

A large and profitable trade cannot fail to be ultimately established in wine, from vines which have been introduced as exotics. Some vines of a fine quality, presented by Louis-Philippe, King of the French, to the late King William IV., have been sent to New South Wales, whose clarets may by and bye rival those of France. Already, from grapes grown in the vineyards of the colony, excellent wine might be produced, if any thing like good management were exercised. From the peaches of New South Wales the finest brandy is distilled: so superior is this article, that, if it were allowed to be imported into Great Britain, it would speedily supersede the use of the brandies of France and other high-priced spirits. Silk (from the abundance of the mulberry) ed fruits, with other valuable articles n and indigo, for the which the climat rable, will doubtless be produced. A rt distance from Sydn orange grove has been formed, from which u 100,000 dozens of oranges have been sent int ket there in a year; and an immense quanti grapes are sent by a steamer from Hunter's Ri day in the season, to the Sydney market. articles of food in general use not produc colony, are tea and sugar; but these are l ported, and sold at perhaps not the third of t in this country. In the advertisements in th newspapers, we see the same kinds of articles a for sale by tradesmen as are seen every whe wealthiest establishments in Britain.

The production of wool has for some time b a primary consideration with the settlers, and of late begun to pay more attention to the qu they did formerly, quantity alone having be time all they aimed at. From the improvem has taken place in the breed of sheep, as well mode of preparing the wool for the market. A wool has now become an object of much inter dealers and woollen manufacturers in Englan it is greatly prized for the peculiar softness of produced from it, and which, if combined wi higher degree of fineness—a result that must low the care and attention that is now bestow —would place it on a level with the best g other countries, and consequently direct an i tible stream of wealth into the colony; and t two important considerations at this moment to produce this effect. The first of these is the of the market, and the fair remunerating pri the settler obtains for his wool; the next, the which the distance of the extensive interior se from towns imposes on their occupants, of their whole attention to the rearing of cattle a in preference to agricultural productions.

The state of society in New South Wales to a considerable extent affected by the trans thither of convicts from the United Kingdom that account is less agreeable than that of col from this moral stain. The plan which has bee followed by government on transmitting conv not be particularly described, as no new assig to take place. Convicts now deported are, w sent to Norfolk Island, which may be called a tiary on a great and improved scale.

The most unhappy circumstance connected state of general society is, that the emancipatec and their descendants, however well behaved, as a degraded or inferior class by the free sett thus two factions have sprung up in the col virulently persecute each other, and cause di what would be otherwise an agreeable con affairs. As the settlement of convicts as lab abandoned as a practice unworthy of an en government, it is to be hoped that the line o tion between the two classes of inhabitants dually disappear. In Sydney, where society and good equally flourishes, there are many f of families of the highest respectability, enj the elegancies of refined life, exchanging its c and cultivating its amusements and pleasures; equipages are to be seen rolling along its st public dancing and assembly rooms blazing w and filled, as our newspapers would say, with and fashion;" music parties and theatricals f the measure of the happiness of a Sydney lif to Sydney, Bathurst has probably the highes sions to a superiority in the general charact society. Besides its literary institutions, it h association called the Bathurst Hunt, compos the sporting gentlemen who reside in the distri wear a uniform, and are, as a body, no way in any similar society in England.

The convict system only extended to New Sout

ood water was found. The failure led to the settle-
t on the Derwent River in Van Diemen's Land,
it is rather singular that the first settlers in the
ard effort were from that island: these settlers,
ing crossed the sea (Bass's Straits) to pasture their
ks on the Australian continent, brought the capa-
s of Port Philip into notice, and led to those inves-
tions which have terminated in making it a flourish-
colony. Major Mitchell describes the interior "as
eat resources, of the most various and fascinating
cription, more extensive than Great Britain, equally
in point of soil, and ready for the plough." The
l is well clothed with grass, and requires no clear-
the trees being few. The prevailing plants are
st oaks, honeysuckles, and what are called wattles,
ch belong to the mimosa tribe. The face of the
ntry is diversified by gentle slopes, plains, and vales,
reat fertility, and well watered by numerous springs.
re are few hills; but these are beautifully wooded,
with little labour might be rendered excellent graz-
lands. From the private information we have re-
ed, it appears that a very large portion of the inte-
consists of the usual flat and extensive plains in
ch Australia abounds. These plains are more or
covered with herbage suitable for sheep pasture,
are here and there refreshed with the shade of trees
water-courses.

The capital of Port Philip district is Melbourne, a
ng town situated at the falls of the River Yarra-
rra, a few miles from the harbour. From its situ-
n, the town can always be supplied with fresh water
n above the falls, while immediately below, ships of
tons can be discharged. Port Philip itself is a large
, about forty miles long and thirty-five broad, with
entrance from Bass's Straits, of three quarters of a
e in breadth. It is of such depth, that a vessel of
tonnage may enter and find shelter behind the
ious creeks with which it abounds. Being situated
osite Launceston in Van Diemen's Land, a ready in-
course may be carried on betwixt the two ports. The
ntry around Melbourne is thickly studded with trees,
efly what the natives call the *yarra*, and from which
river has received its name.

The following is an extract of a published letter
m a gentleman residing at Sydney, referring to this
ng settlement:—"I am quite delighted with this
utiful Melbourne. Enthusiastic as I was regarding
extraordinary advantages of this favoured province,
lmost upon my approaching it had some misgivings
t the reality would, as, alas! is too frequently the
e, involve the bitterness of disappointment. The
lity, however, in this instance, far surpassed my
st sanguine expectations, and every day's experience
nfirms me in my favourable opinion of this Australia
lix. The appearance of Melbourne is positively
nderful; a foreigner unacquainted with the enter-
sing, determined, obstacle-surmounting character of
r countrymen, could never believe that it was the
ation of eighteen months' industry. The wand of
magician could not have effected a change more
ndrous. If all the towns on the road from Sydney
Yass were put together—Liverpool, Campbeltown,
ulburn, and Yass, they would not make so respect-
le a town as Melbourne now is. The commercial
portance of Melbourne is evident from the activity
its inhabitants, and the number of ships and vessels
t visit its port (*i. e.* Port Philip). A powerful
am-ship, to trade between this and the neighbouring
tlements, is pressingly required, and would pay her
ners a very handsome profit. I have just returned
m a delightful boat excursion on the beautiful Yarra-
rra, the scenery on the banks of which is most at-
ctive. * * * You are at liberty to make any use
u please of these remarks; their correctness may be
pended on. We feel perfectly convinced, that the
untry around or connected with Port Philip, is a finer
ct than any of a similar extent in Australia, and better
uated in point of locality. It is destined to become
e of the most flourishing provinces of this continent."

Mr Russell, in his tour in the Australian colonies, says of Port Philip—"This is a portion of the Australian territory which has in less than two years gathered a community of about 3500 souls, who have been attracted to the place by its good harbour and superiority of soil. Being more to the south than either Sydney, Adelaide, or Swan River, its geographical position gives it every advantage both in climate and productions. Private enterprise has already raised it to an important colony, through the shipments of its wool to the mother country, besides the flocks of superior sheep sent to South Australia, &c., and even mutton to Van Diemen's Land, thereby returning to that fertile island their own sheep, after being fattened on the soil of Australia Felix." From tables in Mr Russell's work, it appears that, in 1837, 56,326 acres of land were sold in this district, for which the sum of L.69,099 was obtained, and that chiefly from individuals well acquainted with the capabilities of an Australian soil. The first settlers came from Van Diemen's Land and New South Wales to Port Philip, preferring it to the older settlements; and these being in almost all cases young men, a spirit of enterprise was at once set agoing, which has been since of the greatest benefit to the colony.

Besides Port Philip, Australia Felix also possesses an excellent station for a town, in Portland Bay. This bay is rather exposed to a heavy swell during four months of the year, which renders landing in it dangerous; but during the remaining eight months the winds blow off the land, when it is perfectly safe. The interior, for seventy miles back, according to Mr James and others, exhibits one of the richest and most desirable countries in the world, fit either for grazing or for the plough. Mr James thus speaks of Portland Bay:—"To the north-east of Portland Bay are fine sheep and cattle runs, until you come to the lakes; and here may be seen large flocks of Van Diemen's Land sheep depasturing all the way up to Mount Macedon and down to Geelong. The country about Cape Otway is rocky and mountainous. This cape is opposite Bass's Straits, which are only forty miles broad at this part; and at the back of the highlands of the cape the grass is good, though the fresh water is not so abundant as in the rear of Portland Bay." This district is about 700 miles overland from Sydney, and the road is good and well marked.

SOUTH AUSTRALIA.

South Australia is a large district of country, lying on the southern shore of the Australian continent, between the Swan River settlement or Western Australia on the west, and New South Wales on the east. It is contained within the 26th and 36th degrees of south latitude, and forms a territory of nearly 300,000 square miles, or 192,000,000 acres, being nearly double the dimensions of the British Isles. It is penetrated from the sea by Spencer's Gulf and Gulf St Vincent, at the entrance of which lies Kangaroo Island. The country from the eastern side of Gulf St Vincent is very picturesque; being in general well wooded, with considerable spaces of open country. This renders it admirably adapted for sheep farming, and in many places the land is ready for the plough.

About ten or twelve miles inland runs a range of hills, most of which are good soil to the top, and afford abundance of food for cattle. The highest of these is Mount Lofty, which is 2400 feet above the level of the sea. The country between these hills and the sea is diversified, being in some parts undulating and in others level.

Gulf St Vincent is described as without an island, rock, reef, or sandbank, and almost any part of it is perfectly safe anchorage all the year round. Spencer's Gulf runs nearly 300 miles into the interior, becoming quite narrow and shallow at the top. It abounds with fine fish; but the country around is deficient in fresh water, and but a small portion of the soil is capable of cultivation. The great want of this colony is rivers, by which an intercourse with the interior could be effected. The largest river is the Murray, which is desc Mr James as being, for the last 200 miles of it nearly as broad as the Thames at London Brid the banks of this river are several fine alluv at present covered with reeds, but which are of being made to yield abundant crops of grain. flats are nearly on a level with the river, and irrigated at any season. The Murray delivers it into Lake Alexandrina, which also receives th of the Hindmarsh, and from thence to the sea is broad and deep. The next river is the Tor the banks of which stands the town of Adel capital of the colony. The site of the town chosen as to the healthiness of the situation, but under the disadvantage of being six miles from bour, betwixt which and the town the carriage is very expensive. The harbour is perfectly shipping, but there is a bar at the entrance wh vents very large ships from entering. The g jection to the site of the town is the want of goo which can only be obtained by boring to the about forty feet, or taking it from the Torren degenerates into almost stagnant pools in the dr The town of Adelaide has several good stone a houses, and the churches and public offices scribed as handsome buildings. The River Gl the eastern boundary of the colony, is of cons size during the winter months, but is almost dry mer. Lake Victoria is a sheet of water abou miles long and seven broad, communicating Murray River by a stream called the Rufus. abound with good pasturage, and the country being flat, it might be made an admirable agri station. Lake Bonney is smaller than Lake but the land around it possesses equal advanta regard to soil.

Much has been written upon the soil of Sou tralia. On the one hand, it has been lauded finest spot in the world, and on the other decrie worth the trouble of cultivation. From the be rities we have been able to consult, there appea very little of what can be called really barr The principal part of it is fit for grazing sh cattle, and there are many parts which would abundant return of grain if subjected to the On this subject Mr James, who is known not to favourable to the colony, says, "In short, the re good soil than will be required for many years it is generally composed of a rich loam, averagi nine inches thick, on a substratum of coarse ca rock, and, through the whole extent of the plai the settlement, gives evidence of having been at remote period covered by the sea, every stone up being a part of the rock, and exhibiting a c of little shells. Over the hills the soil and ve are still finer; and the author visited a tract of between the mountains and the mouth of the that seemed to contain nearly 100,000 acres of c rich soil, in many places ready for the plough."

From the want of mountains, the country is v from rains, and even the rivers become compa dry during the summer. These deficiencies ar the grand drawbacks upon this otherwise fine With respect to the condition of the colony up period, we present the following extract from of the governor (Gawler) to his legislative April 3, 1840:—"The establishment of the col cost a large sum; but it is probable that no province has ever attained to the same condi to say the least, a smaller price. However g expenditure may be, the results are great also.

Three years and a half ago, the spot on w are now standing was a desert unknown to Eur Now we are surrounded by a populous, and, to derable extent, handsome city. Our principal are lined with well-filled warehouses and sho crowded by all the attendants of active traffic some and substantial buildings are to be seen o side, and are rapidly increasing. Our port,

mised by the commissioners, and with such sounces there will not be a finer harbour for vessels ing under sixteen feet water. Ships of larger sions may discharge their cargoes from the gulf, is in itself a secure roadstead. The neighbourof the capital is studded with numerous and popu-

H WALES.

lous suburbs and villages; while the more distant country, whether to the north, the east, or the south, is rapidly assuming, in population, that healthy and natural proportion which it ought to bear to the metropolis.

Farming establishments are in active formation on every side; and it is now a matter not merely of hope but of sober expectation, that our magnificent agricultural valleys will soon be filled with produce sufficient for home consumption. Flocks and herds of cattle from New South Wales, following each other in countless succession, already cover a tract of two hundred miles in length; and their enterprising proprietors are even now seriously contemplating a noble attempt at geographical discovery, which bids fair to make this province the great entrepôt of South Australia. Our institutions are assuming a condition of stability. Our public departments have attained to a high degree of system and order. The aborigines have been kept under humane control; and considerable, though I regret to say, as yet unsatisfactory efforts, have been made towards their civilisation. Property and private rights enjoy as much protection as in any country in the world; and peace, union, and good understanding, reign throughout the community.

Land has been surveyed, to an extent capable of containing three times the present amount of population; and the most promising arrangements are in active operation, for completing, in a comparatively short space of time, the survey of those rich and beautiful districts already discovered, which would enable us to increase it from ten to twenty fold."

We add the following from articles in the South Australian Register, July 1840:—"In the last general notice of the progress of South Australia, published in August 1839, the population of the colony was stated at 8500. This amount, we have since ascertained, was almost exactly correct. The arrivals since that period have increased the number to nearly 13,250, of which about 6700 are located in Adelaide and the villages in its immediate environs, and the remainder distributed throughout the agricultural and pastoral districts. On the 30th June 1839, the stock in the province was as follows:—Sheep, 58,500; bullocks, cows, &c., 6250; horses, 520; pigs, 1000; goats, 150. On the 30th June 1840, the colony possessed 136,000 sheep; 14,800 head of cows, &c.; 1250 horses; 3600 pigs; and 350 goats—showing, at the close of one year, an *increase*, after satisfying the large consumption of the population, of 127,000 sheep, 8550 cows, heifers, and bullocks, 730 horses, 2660 pigs, and 170 goats. In the above number of sheep we have included 13,000 which have arrived overland from New South Wales during the present week. From advices just received, we learn that upwards of 40,000 sheep, 3000 head of cattle, and 500 horses, are now on their route overland, and may be expected within the ensuing three months.

The prices at the present moment may be quoted as under:—

Sheep,	£1. 6s. to £2. 2s.
Cows and heifers,	9. 0s. to 18. 0s.
Bullocks and steers,	10. 0s. to 21. 0s.
Horses,	35. 0s. to 130. 0s.
Pigs,	1. 5s. to 7. 7s.
Goats,	2. 0s. to 6. 6s.

One of the most frequent, and, at the same time, most unjust and inconsiderate subjects of reproach, is, that we 'grow nothing'—that we 'produce nothing.' Now, whatever may be the faults or errors of the colonists, we must deny, in the most unequivocal manner, that there is any thing of the *festina lente* in their character or proceedings. The first handful of settlers, in 1837 and 1838, could not fairly be expected to grow an ample supply of grain for themselves and for the thousands of emigrants that were pouring in upon them. During the two first seasons of the settlement of South Australia, it must not be forgotten, they *had no land surveyed and appropriated, whereon they could proceed with their farming operations.* In point of fact, last year was the first in which it was practicable to commence grain growing. Nearly 500 acres were fenced in and cultivated. At the present time, a ing to the most careful estimate we have been make, the number of acres, in wheat alone, 1600; and before the middle of November, we that there will be, in maize and other crops, thre the province, considerably upwards of 2000 Judging from the activity with which fencing ceeding in all directions, we may safely state the of land which will be cultivated in 1841 at 12,00 It is thus most gratifying to prove, that so far f colonists being obnoxious to the charge of 'd thing,' they have been most actively engaged in the unlimited agricultural capabilities of the c good account. We are fully warranted in a that the harvest of 1842 will see South Australia independent of our neighbours for supplies c A few years more, and the probability is we able to supply them."

From a statistical return, June 1840, we c following particulars:—

"*Stock.*—Sheep, 180,000; cattle, 15,000; 1500; pigs, 3600; goats, 400.

Shipping.—Ships arrived in the port, 104; 19,399; ships from Europe, 18; ships in harb tonnage, 3059.

Rural lands—number of acres selected.—Di 43,086; district B, 21,058; district C, 16,000; D, 1040; district E, 7536; district F, 480 number of acres surveyed, 359,975. Special of 4000 acres each, 36.

Houses in Adelaide.—Brick or stone, 816; 1588; churches and meeting-houses, 8.

Wages.—Carpenters, 12s. to 15s.; masons a layers, 12s. to 14s.; labourers, 6s. to 7s. p Men-servants, L.25 to L.60; women-servants, L.25 per annum.

Price of stock.—Sheep, 25s. to 40s.; cows, L.18; oxen, L.12 to L.20; horses, L.30 to L.1 L.2 to L.6; goats, L.3 to L.6.

Imports.—[These we omit, as they are such be expected.]

On comparing this return with the one compil end of 1839, it appears that the increase, during six months of the past year, was as follows:— tion, 2000. Sheep, 93,604; cattle, 7000; hor pigs, 600; goats, 100. Number of acres se district A, 736; district B, 1920; district C, 5 trict D, 1040; district E, 1626; district F, 16 number of acres surveyed during this period, Houses built, brick and stone, 403; wood While sheep have fallen about 20s., and catt L.4 each, wages remain the same."

WESTERN AUSTRALIA.

This colony, which is entirely distinct fr South Wales, includes the settlements at Sw and King George's Sound. Swan River settlem its name, as is obvious, from the river in wh nity it is. This river is situated on the south-w of Australia, a little way north of the most southern point, on the west side of the isla neighbourhood was first proposed as a place ment in the year 1828, when Captain Stirling pointed lieutenant-governor. The latest acc the progress of this little colony are upon t favourable, although they do not certainly hold very great inducements for any one to go thit

The soil appears, and really is, until you h about fifteen or twenty miles inland, extrem and barren. At this distance from the coast, it greatly improves, exhibiting many beautiful tile tracts, and bearing some of the most ma trees in the world. Here, also, is the same p of those gorgeous flowers which form so rema feature of the natural vegetable productions South Wales and Van Diemen's Land. Its ani ductions are entirely similar to those of the tw colonies, and it is equally free from any t

to man. The heat, however, would appear oppressive than in either of the places just Whether this arises from a greater intensity s rays, or from a lighter or more irregular f those cooling breezes which prevail in both Wales and Van Diemen's Land, is not ex- ut the complaints by the settlers here of the the climate are frequent, while there are s particular from either of the former. The wever, is exceedingly salubrious. Not only mplaints of any kind whatever, attributable ntry, appeared amongst the colonists, but enabled to bear exposures with impunity, nost other climates, might be attended with erious consequences.

t land, indeed the only land, yet discovered near the settlement worth cultivating, is on of the Swan River, and on those of an ad- er called the Canning; but even there it nds on either side more than two miles from), and not often so far, and all this land has dy located. There is, however, reason to be- good tracts of country are to be found in the ndeed some have been found: but the young not yet had time to devote to expeditions of or been able to avail itself of those that have . The pressure of emigration, however, and re on the part of those already there, will no soon extend the dependencies of the settle- lead to some valuable acquisitions of country. lready under cultivation has been found to oductive, bearing crops of wheat and other al to the best of any other country, but not ficient abundance to supply the wants of the For grain, and many other articles of agri- oduce, it is still indebted to New South Wales, en's Land, and the Cape of Good Hope; but ss which it has made, and continues to make, leave it at no distant date wholly independent aid.

re already several thriving little towns in the ongst these Freemantle and Perth; the for- ort, being built at the mouth of the Swan l the latter the capital. The site of Perth is d as happily chosen. It is situated on a pictu- t on the north bank of the river, about twelve niles above Freemantle. A government house be built here, and there are many others, lly built of both brick and stone, fast rising s. Colonel Hanson, who has lately published ting account of the Swan River settlement, f this infant capital, says—"The society of is hospitality personified; for though their somewhat limited, yet they share them with t good will." The intending emigrant to that herefore, may look forward to at least a kind from his countrymen who are already there; s no small matter to a man who has just ar- ranger in a foreign land, in which he is in all y to spend the remainder of his life, and is just about to engage in an arduous struggle pport of himself and his family.

KING GEORGE'S SOUND SETTLEMENT.

s little in this settlement that can be consi- uliar to itself, as all its natural properties and istics are the same with those of Swan River. to and is a dependency of the latter, and is n the south side of that point or projection of h places Swan River on the west coast of New

Farmers, labourers, mechanics, and whale , are greatly wanted here, and are offered the encouragement, by authority of Governor to emigrate thither:—A guarantee will be lesired, to such as wish to secure employment aving home, of certain wages proportioned to ities and industry, and regulated by their diffe- es; these wages assured to be about one-half a what is given in this country. They will be also ensured of a supply of provisions at a rate not exceeding a fourth more than the prices of this country. To those who prefer devoting themselves to agricultural pursuits, a grant of land, at the rate of one hundred acres to each family, will be made, free of all charge, with the advantage of fixing the prices of stock, provisions, &c., before starting; thus enabling the emigrant to form a correct idea of the amount of capital which he would require before leaving his native land—a piece of information which is often much too long of coming, sometimes not until it is too late. It is recommended that all who go thither should be married persons, and that they should be accompanied by their wives.

SALE OF LANDS.

With respect to the sale of lands in these colonies, we cannot do better than give the official answer to a letter which we sent to the Colonial Office for information:—

"Colonial Land and Emigration Office,
9, Park Street, Westminster,
1st December 1840.

Gentlemen—I am directed by the Commissioners of Land and Emigration to acknowledge the receipt of your letter of the 12th instant, referred to them by direction of Lord John Russell; and, in compliance with your request, that you may be furnished with the latest government regulations for the sale of crown lands in the colonies, mode of sale, and other particulars, I am desired to transmit to you the under-mentioned papers, which have been printed under the authority of the commissioners. [Here certain papers are mentioned.]

It will be seen by the papers referred to, that, in the Port Philip district of New South Wales, and in Western Australia, the public lands will be sold at one fixed price, which is for the present established at L.1 per acre.

In Lower Canada, the public lands are also henceforward to be sold at a fixed price. In the county of Ottawa, and the county on the south bank of the St Lawrence as far as the Kennaba road, the price is for the present fixed at 6s. per acre, and for the remainder of the province at 4s.

In the following colonies, sales are made at auction, and take place at stated periods, the land being offered at the respective upset prices named in the undermentioned list:—

Sydney district of New South Wales, comprising at present all parts exclusive of the Port Philip district,	12s. 0d. per acre.
Van Diemen's Land,	12s. 0d. ...
Ceylon,	5s. 0d. ...
New Brunswick,	2s. 6d. ...

In Nova Scotia, the upset price is at the discretion of the governor in council; but by a local act, it is in no case to be less than 1s. per acre.

In Upper Canada lands continue to be sold by public auction, at an upset price to be fixed from time to time by the lieutenant-governor in council. This price varies according to the locality, but the average price of land in 1836, 1837, and 1838, was 8s. per acre.

In the Port Philip district, and in Western Australia, it is intended, as you will perceive by the enclosed printed papers, to divide the land into lots of 320 acres, or half a square mile. In Canada the lot has generally been 200 acres; in Ceylon, 100 acres. In Van Diemen's Land, and the Sydney district of New South Wales, the size of the lot is one square mile, except under special circumstances.

The several prices above mentioned will, of course, be subject at any time to revision by the proper authorities. For additional particulars, I am directed to refer you to the parliamentary paper ordered to be printed by the House of Commons, on the motion of Mr O'Brien, on the 18th July last. I have the honour to be, gentlemen, your obedient servant,

S. Walcott, Secretary."

Here follow two of the chief papers referred to:—

"*Notice to Persons desirous of purchasing Land at Sydney or Port Philip.*

1. With a view to promoting settlement in the Australian colonies, the following measures have been adopted, under the sanction of her Majesty's government:—

2. It has been determined that, for all purposes connected with the disposal of land, that portion of the territory of New South Wales which lies to the south of the counties of Murray and St Vincent, and of the Rivers Murrumbidgee and Murray, as far as the eastern boundary of South Australia, shall be separated from the rest of New South Wales, and be distinguished by the title of the Southern or Port Philip district.

3. Within the Port Philip district, land will henceforth be sold at the fixed uniform price of L.1 per acre, in sections of one-half of a square mile, or 320 acres each.

4. Towns already laid out, and in which any land has actually been sold, will be exempt from the operation of the foregoing rule, and town lots in them continue to be sold by auction; and the government will also have the power, should it be deemed expedient, to reserve any sites of towns likely to become the seats of local administration, or any sites eminently adapted for commercial sea-ports. The formation of all other towns and villages, including therefore every inland town, except where the residence of a government may be established, will be left to the enterprise and judgment of individuals.

5. Certain lands, to be properly marked out in maps exhibited at the land-office in the colony, will be set apart for roads and other public purposes, and will be regarded as inalienable public property. But it is not intended, unless in very special and rare cases, to make any reservation of minerals, and all deeds of grant, therefore, will convey to the purchaser every thing above and every thing below the surface.

6. Purchasers in the colony must buy their land at the office for crown lands in the district of Port Philip.

7. Purchasers in England will have to deposit their purchase-money with Mr Barnard, the crown agent for the colony, No. 2, Parliament Street, from whom they will obtain a receipt, on production of which at the office of the Colonial Land and Emigration Commissioners, No. 9, Park Street, Westminster, they will be furnished with an order, stating the number of acres which they have purchased, and directing that this quantity shall be granted to them upon their naming in the colony the spot of unappropriated land which they shall select.

8. The charts and registers to be kept in the land-office at Melbourne are intended to furnish full and authentic information of all appropriations of land, and of all surveyed lands not appropriated, and of all portions of land reserved for public purposes. And each purchaser will be allowed to select his land in the order of his application at that office.

9. Any one who shall pay in this country, or in the colony, the price for eight square miles, or L.5120, will not be confined to districts already surveyed and open for sale, but will have the privilege of demanding a special survey of the land he is desirous to acquire. This land, however, must be taken in one block, of which only the outer boundaries, therefore, will be surveyed. It will also be subject to all regulations which may be established in the colony, respecting the proportion of front to depth, water-frontage, reserves for roads, and other conditions of similar nature.

10. Every purchaser will be entitled to name a number of persons of the labouring class for a free passage to the colony, in proportion to the amount of purchase-money which he has paid in this country: viz., for every L.20, one adult person of fourteen years and upwards, or two children between seven and fourteen, or three children under seven. The whole must be subject to the approval of the commissioners, and fall within their general regulations on this subject, of which a copy will be furnished to any person requiring them.

11. Persons who may wish to avail themselve above advantage, will be required to send into t lists of the names and descriptions of the peo propose for a free passage within six months of of their purchase, after which time no further any nomination for a free passage will be a Purchasers of special surveys, however, will be eighteen months.

12. In the older parts of New South Wale tuting what will henceforward be called the district, land continues to be sold by auction at price of 12s. per acre, in lots of 640 acres, or on mile.

13. Should any person, intending to purch in this portion of New South Wales, think p deposit money in this country, in the mode abo tioned, he will receive from the Land and Em Commissioners an order entitling him to cre corresponding sum in the acquisition of lan public sales in the colony, and he will be all nominate emigrants for conveyance to Sydne the same rules and regulations as above referr the district of Port Philip.—By order of the b

S. Walcott, Sec

Regulations for granting free passages, allu the above paper:—

"1. The emigrants must belong to the clas chanics and handicraftsmen, agricultural labo useful domestic servants. All the adults capable of labour, and emigrate with the inte working for wages after their arrival.

2. Persons, therefore, who are proceedin colony to buy land, or invest a small capital are not eligible for a free passage.

3. The classes most in demand may be desc follows:—shepherds and farm-servants; th employed in building, such as carpenters, join terers, bricklayers and stone-masons, quarryr brickmakers; country blacksmiths, who can sho wheelwrights, and a moderate number of tai shoemakers.

4. The emigrants are required to consist pri of married people and their families.

5. Single women without their parents, are missible if they are emigrating under the im care of some married relatives, or else atta domestic servants to ladies going out as cabin pa in the same ship.

The most useful of this class may be said t mestic servants, as just alluded to, sempstre young women accustomed to farm or dairy wo

6. Single men cannot be allowed, except in a not exceeding that of the single women in t ship. If named by a land purchaser, they can accepted in case the same party has named a number of single women who conform to regul

7. The age of persons accepted as adults is less than fifteen, nor, generally speaking, mo thirty-five. But the latter rule will admit of h laxed in favour of the parents of sons and da of useful ages, going by the same ship.

8. Good character is indispensable, and deci tificates will be required both to this point and competence in the professed trade or calling of posed emigrant.

9. All applications, therefore, must be mad form hereto annexed for the purpose, duly fille attested, as explained in the form itself, and t warded to this office.*

10. For the present, the limited amount does not admit of giving free passages except grants named by parties who have made pure this country of colonial land. No others, theref apply, as it will be impossible to comply with t plications.

* [Applicants, we believe, can procure these blank from shippers of emigrants, who will also show how the filled up.]

nd it is perhaps not too much to say, that fifty
families could be accommodated from Great
nnually, for a century to come. Two or three
s peculiar in the adaptation of Australia to
Some parts are well suited for carrying on
re and gardening; but, from the dry nature of the climate, the grand object of pursuit must be sheep-farming, and it may be recollected that America and England will take any quantity of wool that can be sent, and for which food, clothing, and all desirable articles, will be given in return. Hence, to become a pastoral farmer may be considered the prime intention of the emigrant who possesses a sufficiency of capital, and to employ themselves as shepherds or to work as mechanics is what all labourers without capital will naturally turn to.

The rapid extension of pastoral farming in all the settlements, particularly New South Wales, Port Philip district, and South Australia, and the increasing size of towns, along with the stoppage of convict assignment, have caused a most extraordinary demand for labourers, and wages are very high. In a letter from a gentleman at Melbourne (Port Philip), dated July 23, 1840, to his father in this country, and which has been obligingly shown to us, we find the following passages: —"Melbourne is spreading out daily to a great extent. Labour is the cry. We have had three ships from Mr Marshall of London, during the last three weeks, each vessel bringing at least 200 emigrants; yet the wages are 12s. per day for mechanics, 8s. per day for labourers, and shepherds L.35 per annum, with rations; female house-servants, L.20, and female cooks, L.25 to L.30 per annum, with board and lodging. These are the wages now, and no prospect of a fall. No sooner does an emigrant ship arrive in the bay, than numbers go down and engage servants, and before a week has passed, they are all taken up." It is true, the expense of living is higher at Melbourne than it is in this country, but we should suppose not more than a fourth can be reasonably deducted from the rate of wages on this account; and it is very certain that no man or woman of honest character, who is willing to work, need lack the means of a comfortable mode of life, besides the prospect of still greater advantages.

So great is the demand for labourers, that government, as we have seen, hold out the inducement of a free passage to young persons of both sexes, and a portion of all the money laid out in land is set aside as a fund wherewith to accomplish this desirable object. Persons in humble life, therefore, who are of the age, and belong to any of the professions named, can now get a free passage by applying to the proper authorities; and as there are shippers who negotiate these free passages in every principal sea-port, very little trouble need be encountered on the subject. They will be supported for ten days after landing, but it is not probable they will be ten hours without getting into work.

Others, who do not come under the class for free passages, or who prefer selecting their own mode of transit, can be at no loss whatever to find vessels fitted for their reception. About the months of March and April of each year, emigrant vessels sail in great numbers to Australia. The same expense, we believe, is incurred for a passage to Sydney, Port Philip, or Adelaide. The common price of passage, including provisions, is, for a single man in the steerage, about L.23, and in the cabin, from L.55 to L.60; for a married couple, somewhat less than the double; and for single females the charge is about L.3 less in the steerage, and L.5 in the cabin. Children are rated according to their ages from sixteen, at three-fourths of the above rates down to six, at one-fourth; when under twelve months old, no charge is made. Each passenger is allowed half a ton of luggage. They furnish their own bedding, and, in the case of steerage passengers, their own spoons, knives, forks, &c. When the passage-money, however, is found to be lower than that stated above, it would be well for the intending voyager to see that the difference is not made up by a deficiency in the quantity or quality of his provisions, or that it is not perhaps much more than compensated by some such arrangement, probably, as putting three grown-up persons into one bed, when there are no ordinary ship beds that can with any degree of comfort accommodate more than two.

re follow two of the chief papers referred to:—

'Notice to Persons desirous of purchasing Land at Sydney or Port Philip.

1. With a view to promoting settlement in the ustralian colonies, the following measures have been lopted, under the sanction of her Majesty's govern-ent:—

2. It has been determined that, for all purposes connected with the disposal of land, that portion of the territory of New South Wales which lies to the south of the counties of Murray and St Vincent, and of the Rivers Murrumbidgee and Murray, as far as the eastern boundary of South Australia, shall be separated from the rest of New South Wales, and be distinguished by the title of the Southern or Port Philip district.

In the first letter, tion at sea, after describing the early part of the age, and a visit to Bahia, on the coast of Brazil, the ter proceeds—"From Bahia, we got two new pas- gers who had come from England, and had been ed to put into this port, in consequence of the bad e of the vessel, which was here condemned, and they e waiting for an opportunity of getting forward to tralia. Both are Englishmen, and uncommonly eable; and we have got a great deal of information n one of them regarding the Australian colonies, in ch he was long resident. He confirms all the ideas d formed of the country of Australia, and considers two or three individuals going to the bush and ing some sheep, is the safest and best way for in- ing a small capital, as a concern of that kind is aged at very little expense, and, with economy, will doubt pay. When stating my fears of an inexpe- ced person not being able to go about the matter perly, he said that in three or four months one would uire all the knowledge necessary; and he kindly , that, if we chose, we might go to his farm in Van men's Land for six or twelve months, and he would ery glad of our assistance, as the shearing time will approaching when we arrive, but would not recom- d settling there, as he considered Port Philip the situation. We are, from this and other circum- ces, resolved, on arriving at Port Philip, and while vessel lies there, to take a turn into the country; should matters be at all as they say, and if we can our bills cashed at a reasonable rate, we intend aining there.

n the 11th we came in sight of land, and by three ock afternoon were pretty close in shore, which put in mind of the Yorkshire coast, precipitous and ky to the water's edge. The land was covered with shwood, and looked wild and pretty; and I did not at all disappointed with our first view of Australia ix, though some of our passengers did. The wind tinued unfavourable for four days, during which we ked out and in, making little progress to the east- d [what a want of a steam-tug here!]; but the ap- rance of the country improved much, being now hed with forest down to the shore, and we frequently inguished fires which the natives raised as signals. land we made first was betwixt Portland Bay and e Otway. On the 17th, we entered Port Philip Bay a very narrow entrance, not more than half a mile ad; but on getting through what are called the eads,' the bay opens up into a fine sheet of water, newhere about thirty miles long and twenty broad. country on each side is richly wooded, and rather h. We sailed up in the afternoon, the bay being as m as a loch, with the sun shining clear and beautiful, making us pleased with the new country. We got ore in the morning, and found that we had to walk miles to Melbourne. The appearance of that town, capital of the Port Philip district, was strange to —a great many brick houses and tents being scattered ut here and there. The price of provisions is asto- hingly high, but is more than compensated by pro- tionately high wages. All the mechanics on board re engaged the first day at 12s. per day, and people lting and coming on board to get them. We had bills discounted—the thirty days' ones at 2 per cent. mium, and we got 5 per cent. interest from the banks deposits; for money lent, the common rate is 15 cent. The price of sheep is high, from 30s. to 40s., after the clipping time they will fall, and so also l the other provisions, as there is promise of an ex- lent crop. This is really an astonishing place, for years ago there was nothing but a few mud huts l tents, and now it is assuming the appearance of a ular town. Already, the port is supplying what

places with cattle and sheep; there are now four square-rigged vessels lying here, one of them waiting for a cargo of wool for London, besides various small craft engaged in the coasting trade. We will go into the country, and should we not meet with any thing to suit us in the way of a situation (for we will not lay out our money till we acquire a knowledge to do so advantageously), we will return to town, and have no doubt of getting employment."

Our next extract is from a letter dated January 1840. "When I wrote on arrival, I did not think it would be advantageous to buy sheep, from the highness of their price. I could have got a situation in a merchant's office in Melbourne, with a salary of L.130, but, after all, did not like taking to the pen again. Having been introduced to Mr ——, we visited his station, about seventy miles from Melbourne, and there we bought 500 ewes. We lived there nearly two months, and got a good deal of insight into the business of sheep-farming; were it such a science as it is at home, I would feel a little afraid of succeeding, but there is really no mystery about it. We left that station the day after Christmas, and proceeded with our sheep about twenty-five miles farther up the country, where we are now settled, and have got our hut erected. It would be impossible to give you an outline of all the adventures we have encountered up to this time, and I am so hurried as to be able to write only in snatches. You will have heard that we are settled in company with Mr —— and Mr —— [two acquaintances], which is for the purpose of avoiding the expense which a small number of sheep take." Here we stop to say, that in a letter from the other brother, it is explained that they had procured a license from government to graze and pasture in a certain district, thus avoiding the necessity of buying land; and the following account is given of the sheep-purchase and plan of settlement:—"We have, after many doubts and fears, fairly commenced sheep-farming, having purchased 1080 full-monthed ewes at L.1, 1s. each, merely as a sort of beginning. There are four of us concerned in the undertaking. We have begun on a very economical system, managing the sheep ourselves, one of us going out with them for a week alternately, while the others are doing any thing about the place. We run the whole in one flock, till the lambing, which takes place about the middle of March, when we will require to take another man. We have one man-servant already, who drives and looks after our bullocks, besides making himself generally useful. The sheep require the utmost care and attention possible. One has to take them out at sunrise, so as to get the dew, and remain with them the whole day, bringing them back at sundown. They require to be always watched, both in consequence of the natives and wild-dogs; the dogs are most to be feared, as they often rush into the flocks by day, and sneak into the pens at night. We have as yet escaped both evils; but I have seen as many as six killed in a flock in one night by the wild-dog. The sheep here are very subject to a disease called scab, but it just requires care in looking after to be kept under. I think, if wool keep the same price, we will get about 1s. 5d. per pound, the produce averaging 3 lbs. per sheep, washed. I hardly think the wool will clear our expenses this year, but then we have the increase always coming on; and although the way we live is far from comfortable, in a wretched turf hut, shut out in a manner from all the world and every sort of society, still I have no doubt the thing will pay."

Speaking of the appearance of the country, one of the writers observes—"The aspect of the country, you are aware, is flat, and appearing at a distance as if thickly wooded; but when you enter this woody district, you find generally the trees a good deal separated from one another, with sward among them. This is considered the best ground for sheep, as it affords good shelter from the cold, and shade from the sun. There are really many beautiful parts, and more like the park *scenery around a nobleman's seat* than a wilderness. But there are other places which look as wild as you can conceive—immense plains with n short grass on them—no water—and stretc to the horizon. You cannot see a tree or a them; and they are only inhabited by turkeys, and snakes. The grass in most pa plains affords excellent pasturage for sheep, the want of wood and water, they are use must be near some river or water-holes, in the sheep may drink every day; this they do when there is no rain and the weather ha for some time, when the grass becomes so d you take a little you can rub it in your han like snuff. Our place is very pretty, being or water-holes, which are connected with which we do not know the name. These [or series of pools] run during winter, but in the summer, except the very deep holes. are some large gum-trees, some fallen into and some half buried, but still flourishing, grass long and luxuriant, and forming excell for our bullocks. Our hut is placed a few these holes, with the sheep yard immediate on one side we have a woody country, going body knows how far, affording shelter to th kangaroos, and emus."

From other passages in these letters, we the writers are far from being satisfied with ation—the miseries of living in a turf-built swarms of fleas—the dreadful solitude they pelled to endure, being twenty miles from settlement—their half-savage mode of life— collections of home—all tend to inspire distas lot. We believe that such sensations are all young emigrants who have abruptly le society and plunged all at once into the ne of sheep-farming in the wilderness. It is of i to observe, that no one in such circumstance sonably expect to avoid experiencing such Take any man from a counter or desk, much a respectable drawing-room, and oblige him to the drudgeries of sheep-farming even in Li or Roxburghshire, and he would in all likel precisely the same disgust. But such dis must only have a temporary operation. Aft while, the man's nature will become in some accommodated to them: they will be in th diminished, and other circumstances will aris liate and compensate for them. All, then, emigrant has to contemplate at the beginnin he is to get over the first shock. That passed be hoped that, with a fair share of vigour a verance, he will begin to find pleasures he contemplate in a simple rural life.

The last letter of our two young friends, da 1840, tends to support these views. It is wr much more cheerful spirit than those previo things having begun to improve in appearan lambing season had passed, leaving fully a young lambs, and another dropping equally expected in November; "but," says the write has been a great outlay, and there will be litt till the third year; the wool should then pa penses, the increase of flock being the profit. stock we will have to sell will be wethers, w at present selling for 20s. each." The party begun to cultivate a few acres of land, for th of raising wheat, which is excessively expens colony, also to lay out a garden, and to rear fo only drawback, it is added, is the *want of labou* this keeps every thing behind. The writer n laughs than laments over "the domestic arran of the hut: one of his companions had comm wife from Scotland, and sent for two nephews in the farm, while all were looking forward to of moderate prosperity and comfort.

LAND AND NEW ZEALAND.

gain, very poor, presenting a cold thin soil, of little alue. Van Diemen's Land, though it cannot be called well-watered country, is yet much superior in that respect to New South Wales. Besides several extensive akes scattered throughout the interior, it possesses a onsiderable number of rivers; and in almost every istrict of the island water is to be found. The names f the two largest rivers are the Derwent and the amar.

In another important particular, this island is peculiarly fortunate, that is, in the number and capacity of s harbours, no place of similar extent in the world robably being equal to it in this respect. The principal harbours are—the Derwent on its southern side, ort Davey and Macquarrie Harbour on the western, ort Sorrel and Port Dalrymple on the northern, and yster Bay and Great Swan Port on the eastern coast. esides these, there are many other harbours, bays, nd creeks, distributed all alongst its shores. The oast is in general high and rocky, particularly on the outh, east, and western sides of the island: on the orth, however, it presents a line of low alternate sandy eaches, on which the surf rolls with great impetuosity uring the prevalence of northerly winds. From the xtremely hilly nature of the country, there is but a omparatively small proportion of it adapted for the lough, though presenting abundance of excellent pasurage. The extent of really available land throughout he known part of the island, has been estimated at one-hird of the whole, and this is again divided into four arts, giving one for the plough and the other three or pasture: thus, out of 1000 acres of land, about 100 vill be found fit for cultivation, and from 300 to 400 or grazing. This is, of course, a rough estimate, and nay be found not to be correct in many instances, but n general we believe it will not be far from the truth.

DIVISION—DISTRICTS, &c.

Van Diemen's Land was originally divided into two ounties, Buckingham and Cornwall; the former occuying the northern, and the latter the southern portion f the island. These counties have been again subdivided into the following districts:—Hobart Town, New Norfolk, Richmond, Clyde, Oatlands, Oyster Bay, Campbeltown, Norfolk Plains, and Launceston.

Hobart Town District, though the smallest in extent f any in the island, is yet the most important in the olony, as well from the circumstance of its including Hobart Town, the capital of the island, as from its possessing many superior local advantages; and, amongst hese, that of its being accessible by water on three lifferent sides—by the Huon River, which forms its outhern boundary, by the Derwent on the north and ast, and by the sea on the east. The whole district, ncluding the island of Bruny, which lies off the mouth f the Huon River, and forms part of it, comprises 400 quare miles, or about 25,000 acres. The country in

this district, however, is in general so hilly, that out of these 25,000 acres there are not above 1600 under tillage; and it is said that the first cost of clearing and preparing these lands for the plough greatly exceeds what they would now bring altogether if put up to public sale. The best and principal farms here are situated on the banks of the Derwent, and south of Hobart Town in the direction of Fairlie's Cove; behind this interiorly there are but few locations, nor does the appearance of the country tend much to invite future settlers, the soil being in general so thin, and so heavily encumbered with trees, that even its vicinity to the capital is scarcely an inducement sufficient to any one to attempt its cultivation.

In this district, Hobart Town, the capital of the colony, as we have already said, is situated. Hobart Town is built on the left bank of the River Derwent, at the head of a beautiful cove or bay, distant about twenty miles from its junction with the sea. The town is pleasantly situated on a gently rising ground, which, gradually retiring, terminates ultimately in hills of considerable height, covered with wood, and presenting a most romantic appearance. These, again, are overlooked by one of still greater altitude, called Mount Wellington, which rises to the height of 4000 feet above the level of the sea. Hobart Town is thus happily placed between highly picturesque hills on the one hand, and a beautiful bay or arm of the sea on the other; for, though the Derwent be here called a river, it can be so called only in a very extended sense, the water being still salt, and of considerable width. The town itself covers somewhat more than a square mile of ground; the houses are principally constructed of wood, though many of them are of brick and freestone. The streets are regularly laid out, and those of them that have been completed are macadamised, and present on either side long rows of large and handsome shops. The town derives a peculiar and highly pleasing character, too, from the circumstance of the houses in general standing apart from each other, each having a small plot of ground, from a quarter to half an acre in extent, attached to it. Its public buildings are numerous, and many of them would be considered handsome even in Britain. The town contains breweries, tanneries, distilleries, flour-mills, two or three banks, hospitals, churches, schools charitable and stipendiary, inns, taverns, hotels, and grog-shops *ad infinitum*, and every thing else which bespeaks a thriving, bustling, industrious, and civilised community. Nor are they behind in the department of literature: two or three newspapers are here published weekly, besides a yearly Almanac, containing a great deal of statistical and other interesting information regarding the colony, and an official Gazette.

New Norfolk District lies immediately behind the former, and is entirely inland, no part of it approaching the sea: its extent from east to west is about fifty miles, and from north to south about thirty—thus comprising 1500 square miles, or 900,000 acres. This district is in general much more fertile than that of Hobart Town, returning on an average from six to eight bushels of wheat per acre more than the latter. The farms, too, are of much larger extent, many of them amounting to 2000 acres, some of which are delightfully situated on the banks of the Rivers Derwent and Jordan, the latter of which streams, after passing through an exceedingly beautiful tract of country, ultimately falls into the former at a place called Herdsman's Cove. In this district there is also a large proportion of rich sheep pasture. New Norfolk is intersected, in a north-westerly direction, by a chain of lofty mountains, covered with the most magnificent timber, and exhibiting snow on their summits throughout the greater part of the year. From its vicinity to Hobart Town, and the advantage of water carriage which the lower part of the district possesses, there is a greater proportion of agricultural produce raised in it than in many of the other districts. It is remarkable, however, that, with all its superiority of soil, its crop of potatoes is about one-seventh less than that of the Hobart Town district. Here is a p situated little town or village, bearing the na district, and distant from Hobart Town abou two miles. A coach and van, the former horses and the latter with two, run daily b and Hobart Town; besides these, there is a plying on the Derwent between the two place

Richmond District extends on the sea-co Prosser's River to Tasman's Peninsula, a trac terrupted sterility, being rocky, mountainous, a to the last degree. The ridge of bleak and tive hills which run through this whole le heavily timbered, and never can be made in available to the purposes of man. On the sid Derwent, however, which bounds it on the sout still hilly, there are a number of beautiful a valleys; and around Pitt Water, a salt-water l miles in length and three in breadth, there i derable portion of comparatively level land of description, and well adapted for agricultural In this district there are two towns or villag mond and Serrel; the first fourteen, and th twenty-two miles distant from Hobart Town. latter there are several good inns, a parsona church, jail, &c.; the former is not so well with inns, but there are several respectabl houses. Serrel is situated in the fertile locali Water, and is surrounded on all sides with highly cultivated farms. This district contai ther about 672,000 acres, or about 1050 squa

Oatlands District is separated from the se of the Oyster Bay district, and bounded inte on the west, by the district of Clyde, and on by that of Campbeltown. This district is tively but of small extent, and forms a square thirty miles on each side, containing 900 squa or about 576,000 acres. Though one of the subdivisions of the island, Oatlands is one of possessing, perhaps, a greater proportional cultivatable and grazing land, and that of t quality, than any other locality of similar boun island; its beautiful open and extensive down the richest pasturage, and its arable lands ar fertile and productive with the best in the col is besides most advantageously situated, occ central position between Hobart Town and Lau the next town in the island in extent and impo the former. The advantages which this distr sents have been duly appreciated, and a grea portion of it, taking its limited extent into has been located than of any other distric colony. Coal is found here, but in too remote tion to afford any profit in the working. Wit district are situated what are called the S Plains, a beautiful level tract of fertile country, miles in extent, terminated in the distance ranges of the most magnificent hills. Thes derive their somewhat singular name from thr lakes, or ponds, which are so strongly impregna salt, that they yield by a natural process ma of that essential article of life annually. This not equal in quality to English salt, but, neve brings 10s. a-hundredweight in the colony. T of Oatlands, situated in this district, fifty-one mi Hobart Town, contains a military barracks, a inn, several large stores, and a number of w houses.

Clyde District comprises about 1700 square m 1,088,000 acres. This district is in general hi affords excellent and extensive pasturage. Its ness from Hobart Town, and the difficulty of tra ing agricultural produce to that market, from good roads, has tended to keep it almost exclu pastoral district. The proportion of cultivat here is exceedingly small. Some of the best g farms, however, in the island, are to be found district, many of them covered with the immens and herds of the various settlers. This district advantage of many of the others in the colony

square miles, or about 2,500,000 acres. The greater of this extensive district is wholly useless for any e purposes of man, being barren, sandy, rocky, and ntainous, and in many places altogether inaccessible. withstanding of this, however, it is considered the in importance to the Hobart Town district, from circumstance of its possessing the second largest in the island, namely Launceston, situated at the tion of the North and South Esk, at the head of navigable portion of the River Tamar, which disges itself into Bass's Strait, about forty-five miles w the town. The town presents a very business appearance, with its shipping, wharfs, stores, and ic buildings, all calculated to impress the stranger, on a cursory glance, with a favourable idea of ding importance. The court-houses, soldiers' bars, female factory, &c., stand near to the junction, very fine situation. The male prisoners' barracks ear to the North Esk. There are two finely-built shes here, the Episcopalian and the Scottish Presrian, with numerous and highly respectable conatices. There are, besides, meeting-houses of v other sects, all of whom receive pecuniary supfrom government, in proportion to the number of bers who attend them; also several societies of a volent and useful character, deriving their chief ort from the liberality of the inhabitants. The ange or reading-room, which would not disgrace of the more populous towns of Britain, contains xcellent selection of papers from the other colonies, well as from the mother country. There are sev banking-houses, inns, warehouses, and shops of perior kind, having almost every necessary and ry used in civilised life, and which are obtained at moderate rates. The private residences of the bitants are elegant and substantial, and prove that the architect and the tradesman are to be found is colony. From the favourable nature of its situafor commercial purposes, the river being navigable essels of 500 tons burden up to the town, the trade Launceston is very considerable, and is every day easing. The chief exports are wheat, bark, wool, whale-oil. In connexion with the post-office, custouse, and commercial establishments, a telegraph been erected on an eminence called the Windmill This is of great consequence to the merchants, ascertain, by a code of signals devised for each cantile house, when a vessel either enters or clears heads of George Town; the vessel being scarcely e cove, when the owner or consignee, thirty miles nt, is put in possession of the fact, through this llent medium of communication, where steam-boats tage-coaches are yet awanting. There is a strong ability, however, from the enterprise hitherto dised by the inhabitants, that this want will not have long complained of.

r Russell, a young Scotchman, made a tour in the tralian colonies in 1839, during which he paid a to Launceston district in Van Diemen's Land; from his remarks on the country we offer the folng extract:—

The banks of the River Tamar are of a most rotic description, rather thickly timbered, with here there a comfortable-looking residence, having the cleared in its neighbourhood: the fields produce llent crops. Several flour-mills, &c., are here also, having great facility in conveying produce by s to any place either up or down the river.

he appearance of Launceston harbour, from its ral advantages combined with a class of very enterng merchants, would lead one to suppose that they entering a port in old England. The shipping of this has increased very much of late, both in tonnage in number. Where vessels of 150 tons burden formerly brought up with difficulty, others of 500 now fill their place easily, many of these at present here conveying immense quantities of wheat, flour, hay, to Sydney, Adelaide, and Port Philip, the late ght having caused a scarcity in these colonies,

while this part of the island, from its geographical position and richer soil (though limited), grew crops sufficient to prove its superiority as an agricultural district. Any one visiting the farms on the banks of the Tamar, North Esk, or Norfolk Plains, will cease to wonder at the shipments of grain and other produce. It has formerly been termed the granary of New Holland, and now fully realises the title. Farmers usually get convict labourers assigned to them by government, which is of much consequence, where free labour is yet scarce. Extensive establishments are provided with one or more mechanics; they being of greater value, are estimated as worth two or three labourers, and assigned accordingly. Female convicts are also assigned; the parties binding themselves to furnish all such servants with rations and clothing, agreeably to a government scale furnished them.

There are some fine thriving country towns in this northern district, amongst them Campbeltown, Longford, Evandale, and Perth, which is beautifully situated on the banks of the Esk. Two bridges of considerable dimensions are in process of building across this river, the churches, mills, &c., forming a most picturesque scene. There are also stores for merchandise, and inns for accommodation—two very necessary appendages in country settlements.

The roads in Van Diemen's Land are rather superior, from the quantity of metal always to be had, and the numerous chain-gang parties constantly employed in making and repairing them. Tolls are yet unknown here. In general, the drays used for conveying all kinds of material, are drawn by teams of bullocks, consisting of from two to eight in number, as the occasion requires. The traffic along the different roads with vehicles of all sorts is very great, including mails, stage-coaches, tandems, &c., up to the rolling carriage with liveried servant; some the result of unsurpassed industry, and some through means more equivocal. There are many singular instances in the changes of fortune these colonies have produced on the persons and in the circumstances of individuals sent out here for punishment originally.

The road between Launceston and George Town is at present but a bush one, every one striking off the different turnings as their fancy of saving distance leads them, always converging to the common track at some place or other. At present, however, there are some gangs at work, forming an excellent road, which will soon be in use. I had a good opportunity of seeing the fertility of soil on the banks of the Tamar, when on a visit to a family, and of being still more strongly convinced, that here, as every where else, farming requires considerable attention in taking the advantage of seasons. During the past season, notwithstanding the drought, this industrious class have had excellent returns from their crops. The growth of vegetables, &c., at this farm, particularly attracted my attention beyond any thing I had ever seen in Europe.

Among the many instances of individual enterprise that could be given, is one, where a bridge connecting the north and south banks of the North Esk, was erected through the spirited exertions of a merchant, who is a native, and an honour to the colony which gave him birth. This erection is a fine light structure, and suited for all purposes. I understand that government afterwards compensated this gentleman by some grants of land.

On Norfolk Plains are some extensive and fertile farms, having very excellent steadings. The houses are principally built of brick, having the roofs shingled, that is, covered with pieces of wood similar in size and shape to the common slate.

It has been remarked by almost every one who has visited this island, that cattle and horses thrive remarkably well upon it. The horses used in harness struck me as being much finer than those across the straits, where they exhibit a more relaxed appearance. Here, from the climate being rather cooler, the richness of food grown, and moderate labour, they exhibit plumpness and action at the same time, superior t saw in South Australia. Shortly before my a Launceston, there was said to have been a fin of saddle-horses at the annual races, which to on the course, a flat piece of ground on the ba North Esk, well laid off, and having high la neighbourhood, apparently very suitable for purpose. There is also sport of another kind t with the kangaroo and opossum, which are ve ful on this island. The skins of these animals verted into many purposes, such as shoes, rug

The land on the North Esk, and that which the line of road to Hobart Town through Per and Campbeltown, as far as Oatlands, is toler cleared of timber, and many extensive fields &c., are to be seen. This latter place lies a centre of the island. The country from thence Hobart Town becomes very hilly, with here a a few farms in the valleys; the bush, of course sheep, horses, and cattle in abundance depast its soil. The harvest of Van Diemen's Land commences in February. Around the capital to be some fine spots. The government garde three miles distant, are considered worthy o from the many exotics and fruits grown apples, pears, and all other English fruits, gr great perfection. The grapes raised against are as large as those of Spain or Portugal; bu who has spent much time in all these places this Tasmanian crop deficient. As in the other many of the settlers here have been officers in and navy, grants of land being given them on from active service, which has, no doubt, tend to the formation of an excellent community civilians who ventured their future happiness grating to this island, have been very prospero cipally by dint of determined perseverance."

CLIMATE, SOIL, NATURAL PRODUCTIONS, &c

The climate of Van Diemen's Land is exc pleasant and salubrious, and is especially ad the constitutions of the natives of Great Brit heat in summer is not so intense as that of A not often much surpassing that of London southern parts of England; while the morni evenings, even at the hottest periods of the always cool and agreeable. The cold in wint ever, though mild when compared to what rience at that season, is more intense and o duration than that of Australia, snow lying fr on the higher mountains throughout the grea of the year; but in the valleys and lower di seldom remains more than a few hours. Th net yet appeared any diseases which can be be peculiar either to the climate or to the and, on the whole, the chances of life are e to be considerably more in favour of Van Land than of Britain or any other of the most parts of Europe. Colds are sometimes e winter, but never prove fatal unless negle is not subject to any extremes of heat or c seasons are regular, mild, and agreeable; th sphere constantly pure and elastic; and the s unclouded, and brilliant. The average numbe on which rain falls throughout the year, is f to sixty. The island possesses a considerable of trees and shrubs. The gum-tree is the larg there are numerous others well adapted for house building. The trees are all tall and branching only at the top, and they are nearly greens. The bark of the trees is in general of a complexion as to give them the appearance been peeled, and their leaves are long, nar pointed. All the vegetables and fruits known tivated in England and Scotland, are raised difficulty—apples, pears, plums, gooseberries, which the warmer temperature of Australia vourable, are produced here in great abund of excellent quality. Both the climate and the

erpents nearly the same; its climate being sure, somewhat modified, and its soil in general not ussilly differing in quality. Its animal productions nearly the same with those of Australia, consisting he kangaroo, opossum, squirrel, &c. The native however, as well known in the former country, is

not to be found here; but in its place there is an animal of the panther tribe, which, though it flies from man with the timidity of a hare, is yet extremely destructive to the flocks of the settlers, amongst which it frequently commits the most dreadful havoc. This animal attains considerable size, having been found in many instances to measure six feet from the snout to the extremity of the tail. The birds of Van Diemen's Land are the emu, or Australian ostrich, parrot, cockatoos, herons, swans, pelicans, &c. There are here, too, a considerable number and variety of poisonous reptiles; but these, on the whole, are neither so numerous nor so venomous as in the sister colony.

The seas around Van Diemen's Land abound with whales, dolphins, and seals, and its shores with shell-fish, particularly the mussel, these last literally covering the rocks on its coast, and in its bays, creeks, and harbours. Oysters were once plentiful, but they have become almost extinct.

The leading if not almost the only misfortune under which Van Diemen's Land labours, is a deficiency of good roads. This prevents all communication on a profitable or convenient scale, except in the few cases in which proper thoroughfares have been made. Mr Dixon, a late writer on the country, observes, that the cost of transporting farm-produce a distance of thirty miles, is as great as is the cost of bringing the same quantity of articles from Great Britain; in other words, a barrel of beef can be sent from London to Hobart Town for the same price as it could be sent from thirty miles inland to Hobart Town. If this be true, it is a fact most disgraceful to the local authorities; for without good roads it is utterly impossible to carry on agricultural operations with advantage.* The statistical accounts of the island mention, that latterly great improvements have been made in this respect, there being now upwards of 100 miles of macadamised roads in the colony, also several bridges, and good cross-roads; but we fear that much still remains to be done to extend the means of communication.

GOVERNMENT.

Van Diemen's Land is now an independent British colony. Till the year 1825, it was a dependency of the colony of New South Wales, but in that year it received a government of its own. The internal policy of the island is now conducted by a lieutenant-governor, and an executive and legislative council. There are also here a chief-justice, attorney-general, and all the other appendages of a supreme court of judicature, courts of requests, attorneys, barristers, solicitors, proctors, sheriffs, justices of the peace, and the whole of the paraphernalia of civil and criminal jurisprudence known in this country. There are, besides, as in New South Wales, a number of police magistrates, each having a separate and distinct district under his judicial authority; these are, as in the former case, stipendiary. The laws here are the same with those in England, in so far as the circumstances of the colony will admit. The members of all the civil institutions are appointed by the crown, consisting, in the executive council, of four in number, including the governor, and in the legislative of fifteen, also including that officer. The expense of the judicial department amounts to about L.13,000 per annum, and the ecclesiastical to about L.6500. The military and convict establishment are paid by the mother country. The governor's situation is reckoned worth L.5000 per annum, although his net salary is only L.2500; the difference is made up by taking into account various items, such as furnished houses, gardens, farms, servants, horses, cattle, sheep, pigs, poultry, fish, &c.

Society in Van Diemen's Land, like that of New South Wales, is made up of free settlers who have emigrated from this country, and of convicts. is so much alike in both countries, that it is sary for us to say any thing regarding it in th The convicts in Van Diemen's Land are in all treated the same as in New South Wales, article we refer for particulars. There are gines now in Van Diemen's Land, these hav lately conveyed to an island in Bass's Strait order has been issued by the home govern their removal to Port Philip district, New Sou Regarding the bush-rangers, or runaway from the effective police force kept up, their tions are confined to the less populated distr even there they seldom exist long without b tured. We understand, that while we are no measures are in the course of adoption for altering the mode of convict management an and leaving the colonists to be more depende assistance of free labourers than formerly. information may be obtained on this point o in the colony.

We gather the following information respe condition of Van Diemen's Land from an offici drawn up by the Colonial Secretary to the go for the years 1836–7–8, and published in th Town Courier, 1839. It appears that the fixed of the colony has increased from L.91,320 in L.98,081 in 1838, although in the interval t been a decrease of L.18,000 on the annual reve spirit duties. The number of licenses grante licans and wholesale dealers in spirits has be derably diminished. The annual expenditu colony has correspondingly increased from L in 1835 to L.138,681 in 1838: much of this however, is caused by the colony now bearing of the police establishment, formerly paid by t government. The number of vessels cleared in 1835 was 229, with a tonnage of 55,853; in number of vessels had increased to 370, with a of 64,454. The number of vessels cleared out 1835 was 225, with a tonnage of 53,560; in number was 369, and the tonnage 63,392. The of vessels belonging to the colony had increase years 40 per cent. In 1835 five vessels were the colony, with a tonnage amounting to 382, 1838 the number built was ten, tonnage 1267.

It also appears that the number of acres in increased from 87,283 to 108,000, or nearly 24 The number of horses had increased at the r per cent., and that of sheep from 824,256 to 1 Manufactories and trades are progressively in in almost every branch. In 1835 the number driven by water or wind was 47; in 1838, 51 place of one formerly driven by steam power now two.

PASSAGE.

Van Diemen's Land is sooner reached t South Wales (the distance from Hobart Town ney being about 800 miles); on which acc charge for passage to Hobart Town is in gener pounds less than to Sydney. For a single m cabin, including provisions, it is about L.5 former, and L.55 to the latter; and in the about L.21 and L.23: the difference, in short, L.5 in the case of a cabin passenger, and fro L.3 in that of a steerage passenger—in both sage-money for a married couple is somewhat double. Each passenger is allowed a certain of luggage freight free, generally about ha although in this particular there is a conside ference with different ships, some giving mo greater number less.

SUITABLE OCCUPATIONS.

We have no doubt that in time Van Dieme will form a beautifully cultured and large food ing country, perhaps as much so in proporti size as England. The present preventives of

* Mr Dixon's observations on the state of the roads are completely at variance with those which we have quoted from Mr Russell. Perhaps the roads are good in one or two lines of route, but indifferent in others.

obart Town prices current states wheat to be from
s. to 11s. per bushel; oats, 6s.; hay from L.5 to L.7
r ton; potatoes from L.7 to L.7, 10s. per ton.
The management of sheep and wool is much the
me in Van Diemen's Land as in Australia, and a
scription of it need not here be repeated. To show
e progress which this branch of industry is making in
e country, it may be stated, that the amount of wool
ported in 1836 was 1,985,788 lbs., and in 1837 this had
creased to 2,455,610. From all we can learn, the
crease of stock in Van Diemen's Land is much the
me as in New South Wales, namely, 20 per cent.,
d the loss from deaths, &c., about 5 per cent.
Besides the growing of wool, there is another ex-
edingly promising source of wealth open to the settler
this is the dairy, which seems to be strangely ne-
cted in the colony, although the demand for this
icles of produce is great, and the prices even extra-
gantly high; butter readily bringing 2s. 6d. to 3s.
r pound, and colonial cheese 1s. to 1s. 3d. per pound.
t, with all its vast extent of rich pasturage, and its
numerable flocks and herds, Van Diemen's Land im-
rts both of these articles from New South Wales and
e Cape of Good Hope. Indeed, in the former country,
ere is more than one person who, wisely devoting
emselves to this profitable branch of farm-produce,
e rapidly realising fortunes. Any person, therefore,
ing out with a thorough knowledge of dairy matters,
uld assuredly find his account in it. The cattle in Van
emen's Land are certainly much inferior in general
what they are in this country, and therefore a similar
turn as to quantity could not be expected, but still
at return would be amply sufficient to realise a very
ndsome yearly profit to the dairyman. The person
ing out there, or indeed any other who intends graz-
g cattle, would do well to take with him a quantity
English grass-seeds of various kinds, and particularly
utch clover, which, when once settled, he should
ways carry about with him, sprinkling it here and
ere as he goes over his pasture-lands, as the sameness
the grasses in Van Diemen's Land, notwithstanding
eir richness, has been found injurious to the health
the cattle. On reaching his destination, he will learn
at a little salt also, placed in situations where it may
at once kept dry and be within the reach of his
ttle, will be exceedingly beneficial to them.
The manner of feeding and rearing cattle is in every
spect exactly the same in Van Diemen's Land as in
ngland and Scotland, and their farming is also nearly
e same, differing only in so far as a greater degree of
at in summer requires that it should. There is an
a gone abroad, that all the good land in the island is
ready in the possession of settlers; but this report
incorrect: there are many millions of acres of fer-
e country still to dispose of. Probably by much the
eater part of the best situated lands, in so far as a
ntiguity to market or to points of embarkation is con-
rned, is already in the possession of private persons;
t there is much valuable ground in the interior un-
cupied, particularly a fine newly discovered tract at
e back of Mount Wellington, which will alone afford
cellent locations to all who may seek them for some
ars to come.
A recent writer in the Colonial Magazine, Mr David
rd, a settler in Van Diemen's Land, says, that the
ots occupied form a mere belt along the valley of the
erwent, and that there is abundance of land in other
rts which has not been even surveyed. "There is
uch land, too, which has been despised for its sandy
rface, but a stiff clay generally lies beneath, and it is
ll known what trenching such ground effects. There
e other spots, covered with large surface stones,
most approaching to rocks, that, from the grievous
nt of labour, it becomes almost impossible to con-
rt to a fitness for agricultural purposes, although,
en so converted, they have yielded a most liberal
turn." Land is sold in Van Diemen's Land by public
ction, in lots of one square mile, or 640 acres, at an
set price of 12s. per acre.

The demand for mechanics is equally great in Van Diemen's Land as in Australia, and the encouragement the same. The description of mechanics most in demand here are coopers, ship and house carpenters, cabinet-makers, joiners, wheelwrights, brickmakers, sawyers, quarriers, stone-cutters, and masons. The wages which these receive vary from 5s. to 8s. per day, according to the ability of the workman. Living is said to be higher here than in New South Wales, but from all the information we have been able to procure, articles do not appear to be dearer in the one place than in the other. Beef sells at from 5d. to 8d. per lb.; mutton, 5½d. to 6d.; veal, 8d.; ham, 10d. to 1s.; bread, 1s. 6d. per 4 lb. loaf; oatmeal, 6d. per lb.

Farm-servants and labourers are also greatly wanted in the colony, and readily obtain employment on good terms. Shepherds and good ploughmen receive from L.15 to L.25 per annum, with ample provisions, providing they be trustworthy, and well acquainted with their professions. Common labourers generally receive about 1s. per day with provisions.

Both the mechanic and labourer should be informed, also, that the colonists pay as little in money to any of their workmen as they possibly can, always stipulating for a portion of their wages being taken in produce. This does not apply so much to their principal towns, such as Sydney, Hobart Town, Launceston, &c.; but in the country it is the universal practice. Money, in short, is an exceedingly scarce commodity in the colony, and its place is as far as possible supplied with the produce of the soil.

The following announcement, relative to the conveyance of free emigrants from Britain to Van Diemen's Land, has recently been issued by the Colonial Secretary:—"1. That the sum of L.40 be paid towards the defraying the passage of a man and his wife (and children under three years of age), provided the ages of the married couple do not exceed on embarkation thirty-five years respectively. 2. That the sum of L.19 be paid towards defraying the passage of each female emigrant above eighteen years of age, and not exceeding thirty-five years, on arrival. 3. That the sum of L.18 be paid towards defraying the passage of each female domestic above the age of seventeen years, and not exceeding thirty-five years, on arrival. 4. That the sum of L.7 be paid for the passage of each child from three to ten years of age, and of L.12 for lads between the ages of ten and eighteen, and females between ten and seventeen, respectively, for whose parents or parent the rate of bounty specified in No. 1. may be allowed. 5. That there be allowed to the master of each vessel bringing out emigrants under the terms of this notice, a gratuity of 7s., to the chief mate 3s., and to the second mate 1s. 6d., for each person above one year of age, provided their conduct to such emigrants during the voyage prove satisfactory to the lieutenant-governor. 6. That parties applying for servants under the terms of this notice, be required, before receiving the bounty, to enter into an engagement to maintain them for the term of the agreement hereinafter alluded to, unless parted with by mutual consent, or discharged by due course of law. 7. That persons requiring servants under the bounties thus offered, be allowed to choose their own ships; but it is recommended that regular traders to and from the ports of Hobart Town and Launceston be selected. 8. That no emigrant brought out under the foregoing regulations be engaged for a less period than three years, under a written agreement, according to a form hereafter to be published, and to date from the day that such agreement is entered into in Great Britain or Ireland. 9. That these respective bounties be allowed for emigrants of the following description only:—agricultural labourers, shepherds, masons, bricklayers, blacksmiths, wheelwrights, shipwrights, and all other descriptions of mechanics, and male and female domestic servants."

SEASONS.

The seasons of the year in these colonies being very different from what they are in this country, we offer the following observations on the proper and mode of planting in the kitchen garden, al from the Appendix to the work of W. C. Wen The observations apply to New South Wales in cular, but may with a reasonable allowance useful as regards Van Diemen's Land:—

Potatoes, for a general winter crop in field or should be planted from the end of January to of February, or even the beginning of March, than lose the planting; and they will come into winter, when cabbage and other vegetables run The ground should, if possible, be prepared a before the planting, and a preference given country gardener to new ground, or dry wheat s where the soil is light. The town gardener shou his ground in a good state by frequent light ma In July the ground should be prepared for the s crop, at which time the winter crop will be digging; and in this process care must be taken vent the potatoes being bruised. If possible should be dug in cloudy weather, to avoid expo the sun, which would rot them; whereas, if ca preserved, they will keep sound for a length of a result the more desirable, as at this season veg are generally scarce and dear. The planting shou place in August, or even in September, if nece and at the end of the latter month, or in O they will require to be hilled and earthed, an cleansed from weeds, which must also now and done as weeds make their appearance. In the of seed for this crop, a middle-sized potato sho preferred, without any objection to their being is the customary mode of planting. In October y also plant potatoes for a later crop; and this, perhaps less abundant than that sown in August beginning of September, will nevertheless be suffi productive to pay well the expense and labour of ing. The potato is so essential and desirable an of food, that too much care cannot be bestowed culture and preservation; for should other cro short, this will afford the grower a certain me supporting his family.

Carrots and parsnips, for a general crop, may sown in December and January. The ground be dug deep, and broken up very fine. If the light, the seed should be sown on a calm day, an in. Carrots and parsnips may also be planted i and also in November. They thrive best in an situation, on a light sandy soil; and after they co should be thinned and set out with a small tw garden hoe.

Cabbages, for a constant supply, may be so January, April, May, July, August, October, and in November, at a time when the ground is in a state. The plants sown in April will not run to Care should be taken to set out the plants in a and stronger ground than the bed they are from, otherwise the crop will be poor. Their fir should now and then be weeded with the hand weather, and the freshest and strongest plants re first.

The ground for turnips should be prepared in ruary, and at the latter end of the month some be planted, for which purpose gentle showery we is most favourable. Turnips for a general crop s be sown early in March, and they will be read food for sheep in the beginning of May. During growth they require hoeing once or twice, to thi keep them clean, if the land be foul. Turnips for use may be sown at any time between March and tember, or the beginning of November, when absol necessary.

The seed of cauliflower may be sown at any tim tween November and February, but best in Dece Some sow about the middle of May for a summer and this practice is found to answer.

In March prepare the ground for onions, by b ing it up well, and richly manuring it. At the s

uth, and beginning of April, sow a light crop
ns for immediate use. In April prepare for a
l crop, which should be sown at the latter end of
uth, or beginning of May, to keep them from
o seed. When they grow to a proper size, which
from the latter end of October to the beginning
ember, they should be carefully laid down, so as
break the tops; for should the tops be broken,
e wet penetrate, the onions will inevitably spoil.
fit to draw, they should be gathered on a fine
y, and laid under cover, so as not to be at all ex-
to the sun.

ground should be prepared in March for peas
ans of all kinds, by well working and manuring;
the end of the month, and in April, they may
n for a spring crop. Some sow from the begin-
f March till the middle of June, as occasion may
e. Prepare in August for a later crop: French
may be as well sown in October as at any other

Van Diemen's Land, the farmer sows his grain
y, August, and September, which are the spring
s; in October he prepares the land for Swedish
s; in November he gets in his potato and turnip
; December is the height of his hay harvest; at
the middle of January his wheat harvest com-
s, and continues through February; in March he
ttention to his fallowing and husbandry; in April
bers his second crop of potatoes; in May he lays
his English grasses; and in June he continues
ughing and harrowing. Thus he has a continual
of pleasurable occupation in his fields.

NEW ZEALAND.

Zealand consists mainly of two large islands,
the Middle Island and the North Island, sepa-
by a passage called Cook's Straits, with numerous
r isles scattered around their shores. They lie
great southern ocean in an easterly direction
Australia, and although at a distance of about
niles from that continent, may be considered as
ing to the same division of the globe. The New
d islands lie between the 34th and 48th degrees
h latitude, and the 166th and 179th of east longi-
The southern or Middle Island is about 500
long, and from 100 to 120 broad. The northern
is the smaller, being about 400 miles long,
om 5 to 30 broad; both being estimated to con-
arly 95,000 square miles, of which two-thirds are
cultivation. New Zealand was first discovered
2 by Tasman, who, however, did not land, sup-
; it to form a part of the southern continent.
n Cook first sailed round the islands, and sur-
their shores with so much accuracy, that his
are depended upon even to the present day.
distance of New Zealand from Great Britain is
more than to New South Wales, or about 16,000
but is reached by the same line of voyage round
ape of Good Hope, the return being by Cape
Vessels reach New Zealand from Sydney in
twelve days.

w Zealand is evidently of volcanic origin, there
many extinct and a few active volcanoes in the
or of the islands. According to Mr Darwin, a
alist who visited the islands in the ship Beagle,
soil is volcanic; in several parts we passed over
and vesicular lavas, and the form of a crater
clearly be distinguished in several of the neigh-
ng hills." Hot springs have also been found,
of which are described as higher than boiling
and most of them "of a sufficient temperature to
any kind of native food. There is one spring of
y remarkable quality; it is to the touch as soft as
nd, without the use of soap or any alkali except
the water itself contains, will cleanse the dirtiest
ents, removing every particle of grease, however
sullied they may be with it." A chain of mountains runs through the whole of the southern and a considerable part of the northern island. Some of these mountains are as high as 14,000 feet above the level of the sea, their tops being covered with perpetual snow, and their sides with forest-trees and luxuriant ferns. Besides this chain of mountains, there are other subordinate ranges, which, for the most part, are covered with vegetation to the top. From their volcanic origin, these mountains are studded with large caves; the diameter of whose openings was ascertained in some cases to be above thirty feet. The mountains are all abrupt, and highly picturesque in appearance, the perpetual snow on the tops forming a fine contrast to the agreeable climate and rich vegetation of the valleys below.

There are numbers of fine streams and rivers scattered throughout the country, which have their origin in these mountains. Several of the rivers are navigable to a considerable extent, and possess waterfalls which afford the means of establishing mills in most parts of the country. From the shape of the islands, and the mountains which intersect them, the rivers do not run to any great length, from 100 to 200 miles being the average. In 1838, the ship Pelorus entered a river in the southern island falling into Cook's Straits, and sailed up nearly forty miles, and her boats continued the navigation for twenty miles farther. The River Hokianga, in the northern island, situated almost opposite the Bay of Islands, has been navigated thirty miles by vessels of 500 tons burden. Another river, the Haritoua, which falls into Port Nicholson, is said to be navigable for nearly 100 miles. Besides these, there are numerous streams which cross and intersect the country in all directions, affording abundant means for irrigation where this is necessary.

The bays and harbours of New Zealand are not surpassed either in number or advantages by those of any country in the world. Beginning with the North Island, we have first the harbour of Wangaroa, the entrance to which is narrow, but inside the harbour is spacious and well sheltered. The Bay of Islands is about twenty-five miles south of Wangaroa, and is the harbour which has been hitherto most frequented by Europeans. The entrance to the bay is eleven miles broad, and perfectly safe, there being no bar. Inside, the bay is studded with a number of rocky islands; the water is deep close to the shore, and the anchorage is excellent. This bay has been long visited by whaling vessels for supplies, and a considerable part of the surrounding country is in the possession of Europeans. To the south of the Bay of Islands is the Frith of the Thames, which contains several well-protected harbours. The tide flows in this frith to the height of from eight to ten feet, and at all times there is plenty of water for ships of almost any tonnage. The Bay of Plenty, on the north-east coast, is formed by the island becoming much broader in a curved direction. This bay is very large, and possesses an excellent harbour called Tauranga, which is much frequented for the shipment of flax, &c. Poverty Bay is the place where Captain Cook landed, and, according to him, it affords good anchorage. Hawke's Bay is very extensive and deep, the soundings showing from six to twenty-seven fathoms water. The most important harbour in the northern island is Port Nicholson, situated in Cook's Straits. This is the port fixed upon by government as the future capital of the country, and numerous settlements are now being formed on its shores. The bay is about twelve miles long and three broad, perfectly sheltered, and ships may enter or leave with any wind. The depth of water is from seven to eleven fathoms, and the whole bay is described as of sufficient capacity to hold a navy. The River Haritoua falls into this port, the banks of which are high and well wooded. Port Nicholson has the disadvantage of being upon a lee shore, but this objection can only have weight with regard to the navigation of Cook's Straits, not to vessels lying in the port itself. On the west coast of the North Island the harbours have generally

a bar at the entrance, which render their navigation more dangerous than those on the east coast. The best harbour on the west coast is that of Hokianga, which is said to run nearly thirty miles inland. It receives the river of the same name, and a number of smaller streams; and from all accounts it seems to be a valuable district for settlement. There is a bar at the entrance, with three fathoms water at low ebb; but the tide rises twelve feet, and inside the harbour deepens to seventeen fathoms. To the south of Hokianga occurs the harbour of Kaipara, which is thirty miles long, and receives the waters of three considerable streams. The entrance is obstructed by two sand-banks, but between these the passage is deep, and inside the harbour is safe and commodious.

In the southern island, within Cook's Straits, is the fine harbour of Queen Charlotte's Sound, which is nearly thirty miles long. Ship Cove, within this sound, is a very fine harbour, to which European vessels have long repaired, in consequence of its having been described by Captain Cook. The harbour is perfectly sheltered, and the soundings show ten fathoms a cable's length from the shore. At the north-western extremity of this island is Cloudy Bay, which runs fifteen miles inland, and is about four miles broad. This bay is thought the best station for the black whale fishery, and, in consequence, several Europeans have already settled on its shores. Besides these two harbours, there are many others in the island, such as Lookers-on Bay, visited by Captain Cook, Port Gore, Blind Bay, Admiralty Bay, and others which have not yet been properly surveyed.

CLIMATE.

From the position of New Zealand being north and south, it presents great variety of climate considering the size of the country. All accounts agree, however, in describing it as highly salubrious, and very congenial to European constitutions. Spring commences in the middle of August; summer in December; autumn in March; and winter in July. During winter the temperature ranges from 40° to 50° in some parts, and in others the average is higher. According to Captain Cook, while lying in Queen Charlotte's Sound, the thermometer never sunk below 48° in June, which corresponds to our December. "The trees at that time retained their verdure as if in the summer season; so that I believe their foliage is never shed till pushed by the succeeding leaves in spring." In summer the thermometer ranges from 64° to 80°, which is the highest number given. In Queen Charlotte's Sound Captain Cook says it did not rise higher than 66°, and in the Bay of Islands, in the northern island, a thermometer kept by one of the missionaries "never rose higher than 73° or 74°, nor went below 64°." Mr Yate, in his Account of New Zealand, speaking of the climate, says—"Those who come here sickly are soon restored to health; the healthy become robust, and the robust fat. North of the Thames snows are unknown; and frosts are off the ground by nine o'clock in the morning. The country, during six months in the year, is subject to heavy gales from the east and north-east, which generally last for three days, and are accompanied with tremendous falls of rain. These gales usually commence in the east, and gradually haul round to the north-west, where they terminate in a violent gust almost approaching to a hurricane; the clouds then pass away, and the westerly wind blows again with some violence. In the winter season the moon rarely either changes or wanes without raising one of these tempestuous gales; and during the whole year the wind is sure to blow, though it may be only for a few hours, from the east, every full and change of the moon.

The spring and autumn are delightfully temperate, but subject to showers from the west-south-west. Indeed, however fine the summer may be, we are frequently visited by refreshing rains, which give a peculiar richness to the vegetation and fertility of the land. The prevailing winds are from the south-west and north-west, which, within this range, blow upwards of six months in the year; more frequently the wind is due west. During five months sea-breezes set in from either coast, and meet each other half way across the island.

Colonel Wakefield compares the climate to that of the north of Portugal; and another writer, Mr Ward, to "that of the land lying between the south of Portugal and the north of France—pervading but without exceeding the most favoured part of the temperate region; and numerous witnesses, of ample experience, concur in describing the extremes of cold in winter and heat in summer, as being within peculiarly narrow limits; which is to describe the climate as one of the most equable in the world." Mr Watkins, in his examination before the Committee of the House of Lords, on being asked if the vicissitudes appeared great as compared with European climates, said—"Not anything like our climate. The frost was there at one time a very gentle frost indeed—the ice was not entirely over a small pool of water: they told me that they saw ice sometimes in the bay the thickness of a shilling, but I did not see any near that thickness. I have slept out frequently in the bush. The fern grows in great abundance. I found myself very comfortable and warm in my greatcoat and a bed of fern, rather than sleeping in the houses, which are very unfit for English people."

The climate of New Zealand has one great advantage over that of Australia, in not being subject to the severe droughts which so often destroy the hopes of the farmer in that country. Its insular position, and the lofty mountains which intersect the country, ensure it a constant supply of rain. This circumstance gives it a decided superiority over Australia in an agricultural point of view, rendering it more suitable for the growth of grain; though we are not aware of its being greatly superior to Van Diemen's Land.

It does not appear that there are any diseases peculiar to the climate of New Zealand: all accounts agree in describing the inhabitants as a robust and healthy looking people. Captain Cook says he never saw a single person among them who appeared to have any bodily complaint; and their wounds healed with astonishing rapidity. "A further proof that human nature is here untainted with disease, is the great number of old men we saw; many of whom, by the loss of their hair and teeth, appeared to be very ancient, yet none of them were decrepid; and though not equal to the young in muscular strength, were not a whit behind them in cheerfulness and vivacity." From their intercourse with Europeans, however, many diseases have spread amongst the native inhabitants; the consequence of which is, that in some parts their numbers appear to be on the decline.

SOIL AND PRODUCTIONS.—NATIVES.

The soil of New Zealand appears in almost every part to be excellent, well adapted for cultivating all sorts of grain, and indeed most European vegetables. Around the mountains the soil is volcanic, composed of pumice-stone, somewhat resembling that of some parts of Italy. In other parts, it appears to be a fine stiff loam and vegetable mould, very productive. Captain Cook, describing the valleys, says—"The soil in these valleys and in the plains, of which there are many that are not overgrown with wood, is in general light but fertile; and in the opinion of Mr Banks and Dr Solander, as well as of every other gentleman on board, every kind of European grain, plant, and fruit, would flourish here in the utmost luxuriance. From the vegetables that we found here, there is reason to conclude that the winters are milder than those in England; and we found the summer not hotter, though it was more equally warm; so that if this country should be settled by people from Europe, they would, with a little industry, be very soon supplied, not only with the necessaries but the luxuries of life, in great abundance."

The natives cultivate the potato in considerable quantities, which yields them a good crop without much

l appearance, and is one of the chief ornaments of
woods, but does not appear to be applied to any
ful purpose. Besides these, there are many other
s in New Zealand, especially the pines, which are
l to afford very superior timber for ship and house
ding, and also furniture-making.

The flax is another important vegetable production
New Zealand, and which is likely to form an article
considerable export. It is said to resemble the gar-
is in appearance, having a green thick leaf from
to ten feet long, and growing in the greatest luxu-
nce throughout the country. The fibres of the leaf
this plant are used for making ropes, and many com-
ent judges state that it is better adapted for this
rpose than the European flax. From having been
properly prepared at first, a prejudice exists against
New Zealand flax. Mr M'Donnell says regarding
—" All the standing and part of the running rigging
the Sir George Murray, a ship of 400 tons, belonging
myself, was laid up from New Zealand flax: it had
n over the mast-heads for nearly three years. I
state that better rope never crossed a ship's mast-
d. I have experienced some very heavy gales in
Sir George Murray, consequently the rigging had
n well tried; when lifted and examined it was found
cept where slightly chafed) as good as when first
t over; the running rigging were uncommonly well.
r spars, one and all, were of New Zealand pine—they
re faultless. Cordage and fishing lines made from
d New Zealand flax, have been proved to be far more
rable than any made from European hemp."

The vegetables of Europe have been found to flourish
New Zealand; seeds which were sown by Captain
ok are said to have propagated themselves over a
siderable part of the country. "Large quantities
Indian corn are now raised," says Mr Ward, "and
re is no lack of cabbages, greens, turnips, a parti-
larly fine species of the yam, with other esculent roots.
aches are plentiful in the season at Hokianga; figs,
pes, oranges, melons, and the Cape gooseberry, thrive
ommonly well. There are several species of the
ive fruits very pleasant and grateful to the taste.
awberries and raspberries grow in abundance." A
cies of spinach is indigenous to the country, also a
ruce-tree from which Captain Cook made beer; and
ea-tree which is said to be a good substitute for that
China.

Mr Ward sums up his account of the vegetable pro-
ctions of the country in the following words:—"New
aland is fitted by nature for the production in abun-
nce of those three articles which have always been
garded as the especial signs of the plenty, wealth,
d luxury of a country—corn, wine, and oil. Its
tile plains adapt it to the easy cultivation of grain,
the surplus production of which it will possess a
dy market, from its vicinity to New South Wales and
n Diemen's Land, where, from the high profits of
ol-growing, grain from foreign countries will always
d a ready demand. And the New Zealand harvests
y be safely anticipated to be free from the influence
those destructive droughts which must ever be
inous to the prospects of agriculture in Australia.
e vine has been already found to thrive luxuriantly
the islands, and the possibility of its successful cul-
ation, both for home consumption and commerce,
mits of no doubt. We have previously cited the proof
a strong resemblance to the volcanic soil of Italy in
northern island; and there is good reason to believe
t the wines not only of Italy, but of Spain, Portugal,
d the south of France, might be brought to as great
rfection as in those countries."

The very circumstance of New Zealand being suited
the cultivation of grain, renders it unfit for ever
coming an extensive grazing country, at least for the
owth of the fine wools of Australia. The following
marks from the Sydney Herald newspaper, were
itten by a person who had visited New Zealand on
ren different occasions:—"New Zealand is fitted by
ture to become the garden of New South Wales: the

fertility of the soil, the excellence of the climate, and, above all, the regularity of the seasons, eminently combine to fit it for an agricultural country. But it is only as an agricultural settlement that New Zealand can flourish; as a pastoral country it can never compete with New South Wales. The experiment has again and again been tried, and the result has invariably been the same. The climate is too moist for sheep pastures: and the fine wool for which New South Wales is so remarkable, speedily deteriorates in quality on the transportation of the sheep to New Zealand. The new colony, consequently, can never come into any hurtful competition with New South Wales; on the contrary, the settlement of the former must be highly conducive to the advancement of the latter."

Mr Ward gives the following suggestions for the conveyance of seeds and plants to these colonies, which may not be out of place here:—"The chief articles of produce to be first thought of are such as—1st, call for little labour; 2d, are not bulky for exportation; 3d, suitable for consumption in the colony; 4th, affording a quick return. Fruit-trees have the first requisite. If an emigrant takes out a few bushels of almonds (which we now import from Sicily) they will soon be bearing trees, and either the fruit or the oil is a good article of export. From a hundredweight of raisins of the sun (from the seeds of which a good vine has been known to be raised) he might sow several acres; it would be needful only to plant out the seedlings at the end of the year, and then let them stay till they had borne fruit enough to judge of; perhaps one in a hundred will be worth keeping, and the rest being rooted up, their places might be supplied with cuttings from the good sorts, and in a few years there would be a flourishing vineyard. Or from any of the wine countries, the marc might be procured in a dry state (it is for fuel they keep it), which contains all the grape stones. Of walnuts, the same may be said as of almonds. The kumera or sweet potato, which is well known in New Zealand, has been found in America to make beer exactly like malt; five bushels being equivalent to three. The olive, when once established, may be propagated quickly by cuttings, as also the fig. Plants to be transported by sea should be covered over with a glass hermetically sealed, and never uncovered till they arrive."

Little is known of the mineral productions of New Zealand, no geological survey of the islands having ever been made. Iron and coal are found in abundance, along with bitumen, freestone, marble, and sulphur. A blue pigment made use of by the natives is said to be manganese, and there is a valuable green stone found exclusively in the southern island. There is also abundance of clay fit for brick-making.

There are no native quadrupeds in New Zealand, those at present existing having been left by Captain Cook and other Europeans during their visits to the islands. Pigs are numerous, having spread very rapidly throughout the country. They are said to grow to an enormous size, and are highly valued by the natives. Dogs abound, especially about the Bay of Islands; and cats are also plentiful, and are eaten by the natives. The cattle which have been introduced by the missionaries are said to thrive well. Sheep have also been tried, and in some open parts succeeded; but New Zealand, as already stated, is more of an agricultural than a pastoral country. The only reptile yet seen in the islands is a small species of lizard.

Birds are very numerous, and are described by all travellers as beautiful songsters. Captain Cook says of them—"The ship lay at the distance of somewhat less than a quarter of a mile from the shore in Queen Charlotte's Sound, and in the morning we were awakened by the singing of the birds; the number was incredible, and they seemed to strain their throats in emulation of each other. This wild melody was infinitely superior to any that we had ever heard of the same kind; it seemed to be like small bells most exquisitely tuned; and perhaps the distance and the water between might be no small advantage to the sound. Upon inquiry we found that the birds here always began to sing two hours after midnight, and continuing their till sunrise, were, like our nightingales, silent t of the day."

Amongst the feathered tribe may be mentioned geese, woodcocks, snipes, curlews, and wood-pige affording food to man. These are very numero the wood-pigeons especially are highly valued delicacy of their flesh. They are much larger t pigeons of this country, and are extremely beau plumage—green, purple, and gold, being the pre colours. Some of the birds are very remarkable called by the natives the *tui*, has the power of ing the notes of all the other birds with great exa and may be taught to repeat sentences or imit sounds of quadrupeds. Another, called the about the size of a young turkey, and its plum sembles that of the Australian emu, being long, st and coarse. It has neither wings nor tail, but ru great swiftness along the ground, and can only be by dogs. The natives prize it highly, and mak ments of its skin.

Fish are very abundant all round the coast, a of most excellent quality. "We have," says Mr "a rich supply of salt-water fish; but nothing than eels in any of the fresh-water streams or l New Zealand. Those most plentiful and of g note are soles, mackerel, codfish, a species of s whiting, snapper, mullet, beam-skate, gurnards few smaller kinds, some not so large as a sprat an abundance of cray-fish, oysters, shrimps, p mussels, and cockles. An immensely large measuring from eleven to thirteen inches, is fo great abundance at Kaipara, a harbour on the w coast, and some few of this fish are picked up Bay of Islands. These inhabitants of the deep never-failing resource for the supply of native but fishing is not now much regarded, except mackerel season, when several tribes go together little creeks which these fish frequent, and alwa ceed in capturing some hundreds of thousands they return, the greater part of which they pr for winter stock. They always catch these fish darkest nights, when they are able to see the di the shoal takes from the phosphorescent appe which their motion causes upon the water. Th round them with their nets, which are several hu yards long, and drag them in vast numbers to the where the contents are regularly divided amo people to whom the net belonged."

Whales frequent the coasts of New Zealand purpose of calving, and are caught in large nu This trade alone is very considerable, and wo doubt be greatly extended were settlements mo merous in the country.

The aboriginal natives of New Zealand were fo savage and dangerous, but are now partially imp and harmless in disposition. From all account are susceptible of much greater improvement the natives of Australia, being ready in appreh and tractable. They generally dwell in small v In their intercourse with Europeans, the Ne landers have on all occasions manifested a de learn, and great aptitude in acquiring civilised cu They are very curious to know the use of every they see, not being content with a mere childish ration of it. They make excellent steersmen in and one, in particular, rose to be mate of a coloni sel. Although occasional instances of theft hav known amongst these people, yet upon the whole moral faculties seem to be of a high order.

The missionaries have acquired considerable in over the natives, and have in all cases exercise their benefit. At their suggestion, roads hav formed, bridges erected, and ships of several hu tons' burden built. whole procedure of the company, and of those
with it, forms a singular and striking example
confidence between parties which is only to be
ed in even its simplest forms amidst a commu-
nsiderably advanced in civilisation. Not only
ground of the first settlement *paid for* before
a cognisable existence, but, before its existence
t known in Britain, *nine ships, containing* 1125
nts, had been dispatched to it. There was first
ry, of 382 tons, which sailed on the 4th of May
with only six emigrants, but containing Colonel
field, the company's principal agent for the ar-
ment of settlements, and a great store of articles
ed to be employed in bartering for land with the
chiefs. Colonel Wakefield, it may be remarked,
stinguished himself in the Spanish service, and is
r of the author of the well-known plan of coloni-
followed on this occasion. On August 1st, fol-
the Cuba of 373 tons, with eight first-class emi-
and twenty-two labourers, and containing also
rveying staff, under Captain W. M. Smith of the
rtillery. In the middle of September, the Ori-
Aurora, and Adelaide, respectively of 506, 550,
40 tons, proceeded on the same voyage, with a
body of emigrants of both classes. All of these
rom London. On October 5th, the Duke of Rox-
e sailed from Plymouth with 167 settlers. Three
vessels, one of which was from Glasgow, and two
London, sailed before the end of the year. Besides
there were three ships containing stores, designed
rd against the possibility of any deficiency of neces-
being felt during the early days of the settlement.
voyage of the Tory was prosperous, and uncom-
quick. In ninety-six days from Plymouth, namely,
16th of August, she hove in sight of Cape Farewell,
rthern point of the southern island, and which
one side of the opening, named Cook's Straits,
en the two islands. She lost no time in standing
gh the straits, and on the 18th she anchored in
Cove, as nearly as possible in the same spot that
in Cook occupied in his three visits to the island.
l Wakefield, in his journal, describes the southern
as forbidding in its appearance at a distance—
cession of apparently barren mountains stretching
from the coast till they reach those covered with
n the interior." But, "on nearing the land, you
at the whole is covered to the very highest points
imber and brushwood, which not till then betray
perpetual verdure." Ship Cove, in the northern
, was a beautiful place. "The water, tranquil as
land lake, has ten fathoms' depth within a ship's
of the shore, which is covered to the water's
ith an evergreen forest, consisting of every variety
igenous tree and shrub, so thick as to be scarcely
rable, and presenting to the eye an undulating
of verdure reaching to the summit of the sur-
ing mountains, the highest of which is from 1200
0 feet. The birds, as in the time of the immortal
sh navigator, fill the air with their notes, the
ing of which he has aptly likened to the tinkling
all bells; and the sea teems with fish, of which we
t enough with hooks and lines for the whole ship,
we dropped anchor. These consisted of hauk,
ish, spotted dog-fish, gurnet, flounder, and joe-fish,
which are eatable."

onel Wakefield found no difficulty in communi-
with the native chiefs; but it was not so easy to
re lands, not owing to any disinclination of the
s to sell them at a moderate price, but because it
ifficult to ascertain who were the proper owners,
e owners who could convey a sound title. The
al feeling of the natives is in favour of British

settlements. They have tasted the benefits of civilisation sufficiently, to be very anxious for increased intercourse with the English, and for this reason they appeared to Colonel Wakefield as if they would have willingly allowed the soil to be appropriated to a large extent, without looking for any remuneration. But the company was anxious that a reasonable, and, considering the circumstances, a liberal price, should be given for lands; and the main difficulty, as just stated, was to discover the parties who were entitled to part with the soil. An immense quantity of land had already been appropriated by private persons or by the missionary societies, without much ceremony.

Colonel Wakefield sent home a journal brought down to the 2d of September, and not long after he dispatched another section of it, containing not less interesting intelligence. The second section of his journal commences on the 6th of September with a description of the trade carried on in Queen Charlotte's Sound and other bays connected with Cook's Straits. He describes whalers in the pay of Sydney capitalists as being the chief followers of this hazardous but profitable commerce. It is estimated that the whale-fishery produces 1200 tons of oil per annum, and that the number of British who compose "shore-parties" in Cook's Straits and the stations on Banks's Peninsula, are about 500. They are a lawless set of people, quarrelling with the natives and among themselves. There are, however, some respectable persons among them.

Learning that the church missionaries were endeavouring to frustrate their views respecting Port Nicholson, a fine harbour and country in the northern island, about the centre of Cook's Straits, Colonel Wakefield now made haste thither. He met with a very hearty reception from the chiefs. "Epuri, an old chief, eagerly inquired the motives of our visit, and betrayed the most lively satisfaction at being informed that we wished to buy the place, and bring white men to it. He was followed by Warepori, his nephew, who is about thirty-five years old, and has for some years superseded the older chiefs in influence, by his prowess in war, and skill in the rude arts cultivated by these people." Colonel Wakefield ascended the principal river which falls into the bay, and was well satisfied with the capabilities of the district. The soil is a rich black loam; the timber excellent in quality and of various descriptions; and the navigation of the river, which was obstructed by heaps of stones and trees thrown across, susceptible of great improvement at slight expense.

Colonel Wakefield determined to fix upon this part of the island for the first and principal settlement of the company; and he lost no time in coming to terms with the natives. He thus describes his purchase:—

"I found a territory of forty or fifty miles in length by twenty-five or thirty in breadth, containing a noble harbour, accessible at all times, and in the very highway between New Holland and the Western world, and land exceeding in fertility any I have seen in these islands, and equalling that of an English garden. I found a race of people of warlike habits, and but little used to intercourse with Europeans, just emerging from their barbarism, and inclined to cultivate the arts and intimacy of Great Britain; appreciating the protection from their hostile and still savage enemies that British settlers would afford, and anxiously desiring to assist them in their first labours in a new country. Under these circumstances, and following out the spirit of my instructions, I determined to act in the most liberal manner in the transaction. Moreover, I was most anxious to distinguish this bargain from all others that have been made in New Zealand, that none of the haggling and petty trading which usually take place between Europeans and the natives of this country should enter into any operations between the latter and the company's agents; and that the value of this property should not be regulated by what has hitherto been considered the standard of exchange in similar transactions."

The amount paid, of course, is not published; but the natives were highly pleased with their bar
eager to sell more of their land. The chiefs
examined the articles given in barter, and th
a formal deed, alienating the land for ever.

llowing has been issued by the colonial secre-
pecting the plan of government to be adopted
Zealand:—

The colony is to be entirely separate from and independent of New South Wales. A local legislature, to be composed for the present of the chief officers of the local government, and some of the chief inhabitants, is to be constituted, to make laws for the peace, order, and good government of the colony.

With respect to all lands acquired in the colony under any other than that of grants made in the name and on behalf of her Majesty, it is proposed that the titles of the claimants should be subjected to the investigation of a commission to be constituted for the purpose. The basis of that inquiry will be the assertion on the part of the crown of a title to all lands situate in New Zealand, which have heretofore been granted by the chiefs of those islands according to the customs of the country, and in return for some adequate consideration.

An account of all the just and moderate expenses of the company hitherto incurred in forwarding the colonisation of New Zealand to be made out, and the crown to grant the company as many acres of land as shall be equal to four times the number of pounds sterling which they shall be found to have expended in the manner stated. The lands to be taken by the company in the neighbourhood of their respective settlements at Port Nicholson and New Plymouth.

The company to forego all claim to any lands purchased or acquired by them in New Zealand, other than the lands so to be granted to them, and other than any lands which they may hereafter acquire from the crown, or other persons deriving their title from the crown.

It is proposed to apply to all other British subjects the rule to which the New Zealand Company will be subject in respect of the lands claimed by them within the colony. This advantage, however, will be offered only to those whose lands were acquired before the 5th day of January 1840, the date of proclamation issued by Sir George Gipps on the subject.

The governor of New Zealand will be instructed to recommend to the local legislature the enactment of a law to incorporate, as a municipal body, settlers who have, at the charge of the company, resorted to Port Nicholson, and settled themselves there or in that vicinity. For the present, her majesty's government engage that all sums of money which shall be paid by the company for the purchase of land in New Zealand, shall, whenever such money shall be paid in this country, be laid out in the removal of emigrants to New Zealand, it being left to the company, from time to time, to determine whether such money shall be so laid out by the Commissioners of Colonial Lands and Emigration or by the company themselves, under the superintendence and with the concurrence and sanction of those commissioners. The native reserves made by the company to be sanctioned by the crown.

A charter to be granted for forty years, but to contain provisions enabling the crown to resume the charter and purchase the lands and other property of the company on just and equitable terms, in case the public interest should require such resumption and purchase.

A township has been marked out on the shores of Port Nicholson, and named Wellington, which it is thought will be the capital of the colony. It is also proposed to build a town at the harbour of Hokianga, to be called Churchill; another at the Bay of Islands, to be called Russell; and a fourth at the Frith of Thames, to be called Auckland.

Up till the period we write (April 1841), so little information of a substantial nature has been made known respecting the settlement of New Zealand, that we are unable to say distinctly how the colony is advancing, though, from floating intelligence, there is the greatest prospect of success; ships with emigrants, both capitalists and labourers, and also large stocks of provision and merchandise, are regularly sailing, and the country must soon present the spectacle of general industry and comfort.

SUBJECT OF EMIGRATION CONCLUDED.

In the present and preceding three sheets, we have presented, to the best of our ability, a practical view of the subject of emigration to Canada and other British American possessions, to the United States of America, to the different colonies on the mainland of Australia, and to Van Diemen's Land and New Zealand. These do not comprehend all the fields for emigration, but they are the principal, and those which seem most commonly available. The places of which we have not formally treated, are the Cape of Good Hope, the British West Indies, and Ceylon, all of which are crown colonies, and open to settlers. Ceylon, being situated within a few degrees of the line, and altogether tropical in character, is not to be mentioned as suitable for British emigrants; and the same thing may almost be said of the West Indies. The Cape of Good Hope, consisting of a large portion of South Africa, from all we can understand, is now in a thriving condition, and to many it forms a tempting field of settlement. The climate is agreeable, the government is settled and liberal in character, and there are large tracts of land open to settlers on easy terms. Farms abandoned by Dutch proprietors who have emigrated to more remote districts, can always be obtained at a cheap price; and as respects pastoral qualities, the territory is equal, if not superior, to many portions of Australia. As, however, we have no official papers on the subject before us, we pass to a general consideration of those fields of emigration which have been separately described.

The readers of these sheets will have observed, that each country or district referred to possesses a certain peculiarity of character, or, as we may say, has good and bad points in a greater or lesser ratio, which it will behove the intending emigrant to consider.

Canada possesses a most fertile soil, but it has very indifferent roads, is slow in improving, and labours under the drawback of a long and extremely cold winter. It seems best adapted for small capitalists who wish to pursue agricultural pursuits, or field labourers and artisans of a common kind. It has also the great advantage of being speedily and cheaply reached; yet, to a person with a few pounds to spare, such an advantage should go for nothing. In taking the step of emigration, it is of importance that it should be done well, and once for all.

The United States offer a far more agreeable scene for agricultural labour, because, while the soil is equally fertile with that of Canada, the winters are shorter. Some of the fine prairie-lands of the western states possess attractions which cannot be surpassed. As it is easy to reach these districts from Canada, many spirited emigrants will push on thither if they find such a step advisable. The United States possess a prodigious superiority over Canada in one particular—the sale of lands. In Canada, the abominable plan of selling lands by auction to the highest bidder, at periodic intervals, still continues, and, by disheartening emigrants and wearing out their means, sends shoals onwards to the States, where the land pitched upon has its exact price, and a purchase can be at once effected. If emigrants to Canada, therefore, cannot buy half-cleared lots on the instant, which perhaps they will find no difficulty in doing, we recommend them to proceed immediately into Michigan, Illinois, or some other western state of the Union. They will find so many persons on the road, that the exact route need not here be defined. Were the British government to institute a plan of colonising Canada, on a great scale, with an humble order of settlers, and at the same time permit the free importation of corn from that part of the empire, we might expect to find the country in a state of rapid progression in a very short period of time; but neither of these arrangements is at present likely to be carried into effect. It is proper to mention, that although the United States possess that degree of civil and religious liberty, which leaves nothing to be wished for on that score, the country labours under a universal derangement in money matters, and we fear that the se lay his account with a clumsy and unprofitable barter in relation to most products of his ind

Australia is much better adapted for the e of capitalists than any part of America. hear of any one making a fortune in either the United States, but many in New South V would almost appear that, whatever be th money a man expends on land in America, rises above the condition of a drudge—a cir arising from two causes, lack of cheap labour of outlet for produce. Provided a course o and sobriety be pursued, he will unquestiona a state of competency and tranquillity, and w family rising around him with the prospects able settlement; but we fear that, unless s change take place in Canadian affairs, he slender chance of ever getting above the con small farmer; consequently there is no tem persons of comparative wealth to encounter and annoying difficulties of settlement in country. In Australia, the emigrant will rience personal discomfort and deterioration But a time comes when he can sit down wit of ease, calmly reposing on the advantage earned—he can reasonably look forward to i in refinements such as wealth purchases in and with this pleasing hope, any species of toil is of trifling consideration. Besides, to son who loves a fine climate, where on ea a more delightful country be found than Cold seldom or never sinks to that pitch w duces snow, and the heat, also, is by no m treme. As respects climate and natural we should consider some parts of New Sou equal to Asia-Minor and adjacent countries; British subjects are at liberty to proceed t agreeable field of industry, and there possess a vileges which our laws and constitution best held to be a boon of which we cannot be too There is one material drawback to Australia— of regular and frequent rains. This leads oc to extreme droughts, which parch the groun many parts render the business of the agr very precarious. On that account Australia fitted for pasturage than agriculture. Van Land, and also New Zealand, on the other ha to be more agricultural than pastoral. Grain two grand staples in human affairs, will m become the permanent products of these ferti In point of national economy, it is of no co what a country produces, provided it produce s which can be sold in the general market of t Let the mainland of Australia, therefore, a sperity by its wool, and perhaps its wines and t and let Van Diemen's Land and New Zealan wealth from their grain, flax, timber, and perh whale fisheries. In both New South Wales Diemen's Land, the sales of land are by auct Canada—an evil of serious consequence, from Port Philip district and South Australia are fo exempt.

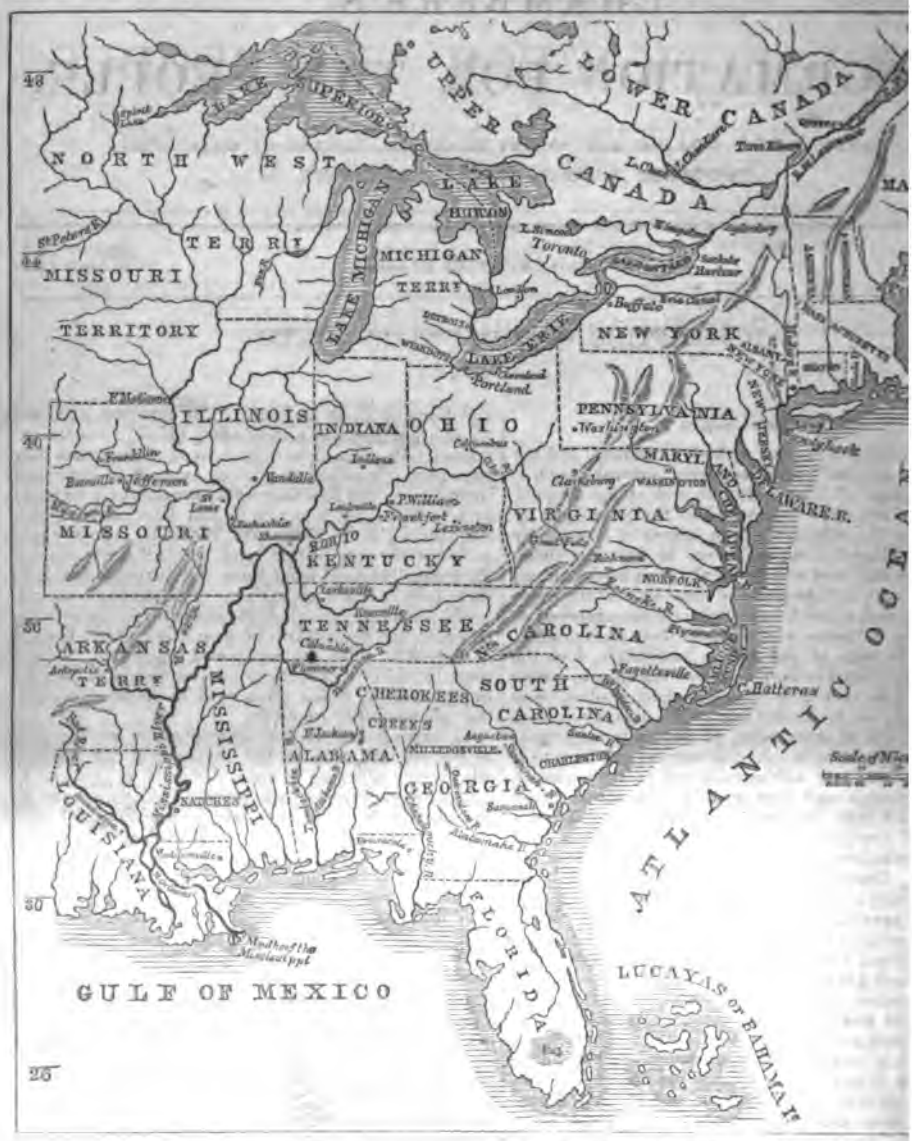
UNITED STATES.

hung on their frontiers. The first tax proposed this purpose was a stamp-duty (1765); but the co- es firmly refused to submit to it, saying that they e perfectly willing to pay the expense of their own ernments, but that they would not endure to be taxed a foreign body like the British Parliament, which situated at the distance of 3000 miles, and in whose berations they had no voice, while it might employ money obtained from them for purposes hostile to r own freedom or welfare. This feeling was uni- al among the people of the colonies; for these being erally the descendants of men who had left Europe disgust at some real or fancied oppression, had not e habits of deference to the commands of persons igh station, which often tend to secure obedience quiet in other countries.

n consequence of this determination on the part he colonies, and of the obstinacy of the English istry in adhering to their demands, a great many tating occurrences took place. The Americans re- d to import or to use British manufactures; riots place in almost all the towns, but chiefly in Bos- ; and the taxed articles which were sent out were troyed. A meeting of delegates from the several nies or districts was held in 1765, to petition and onstrate against what they considered an injustice, l the British government persevered. And though re was at one time an apparent disposition to recede n some of the propositions which had caused most tation, the right of taxing the colonies was vigorously ntained. New taxes were soon after imposed (1767) ea, glass, and paints. The pertinacity of both par- led to frequent violence, and at length to actual onstrations of war on the part of the Americans. s war lasted for about seven years, from 1775 to 2, and concluded at last, as might have been anti- ted, by the British being compelled to relinquish a ntry of which every inhabitant was their enemy. war was conducted on the part of the Americans General George Washington, to whose talents and severance its speedy termination was greatly owing, whose moderation in using the influence which cess had given him over his countrymen, has been seldom imitated by conquerors. The councils of Americans, and their negotiations with other powers, e mainly directed during these transactions by Ben- in Franklin, a man who was equally distinguished a philosopher and a lover of his country.

t the conclusion of peace between Great Britain America, the following thirteen states formed the ublic of the United States:—New Hampshire, sachusetts, Rhode Island, Connecticut, New York, Jersey, Pennsylvania, Delaware, Maryland, Vir- a, North Carolina, South Carolina, and Georgia. these have been added, from time to time, Maine, rmont, Columbia, Alabama, Louisiana (purchased u the French in 1803), Ohio, Michigan, Indiana,

Illinois, Missouri, Kentucky, Tenessee, and Mississippi. Besides these, may be mentioned the territories of Florida, Wisconsin, and Iowa, which are go officers appointed by the American governm



FORM OF GOVERNMENT.

Each of the English colonies, as they settled in America, had had a certain form of government assigned it for maintaining the necessary order. This consisted generally of a house of assembly, chosen by the people, with governor, judges, and other officers, appointed by the king, but paid out of taxes levied by the representatives. On acquiring independence after their war with the mother country, the different colonies, now called *states*, made such alterations, each in its own constitution, as they believed to be suited to their circumstances; and a general government, framed and appointed by the consent of the whole, was formed to take charge of such national affairs as the states could not manage separately. The states have each a senate and house of representatives; the members of the former are fewer in number than those of the latter, *and a part of them* only is chosen at each election, so *that they remain in office* for several years, generally *four: the house* of representatives is elected anew every year. The resolutions agreed to by bodies for the government of the state, are submitted to a president or governor, whos constitutes them part of the law. Both sen representatives are paid for their attendan public business, generally at the rate of two nine shillings sterling) per day, besides an for travelling expenses. The right of electi in the people under certain limitations: in s the possession of a certain property (about quired in the electors: in others, the regular of certain taxes: in all, a residence in the s ing from two years to six months, is requi there are only eight of the states in which bl are allowed to give votes. The judges and oth trates are in some states elected by the people; by the governor, subject to the approval o houses: and their tenure of office is in some of years; in others, during good behaviour; veral, till the holder attain a certain age (abo

ition of the people, to be passed over in silence. rally speaking, it may be said that popular opinion absolute governing power in the States, and can- be withstood by any species of opposition. Popu- pinion, whether right or wrong, enforces uniformity ternal behaviour and profession of belief, to a de- which would be called despotic if exercised in a archical country. On this account, the mainte- e of opinions with respect to politics and religion actically less free in America than in England, e, if a man pay all demands upon him, and commit vert act of sedition or other gross impropriety, he professes what opinions he pleases, and live any way suits his fancy.

he expense at which the entire government of the s is conducted, including the military and naval rtments, is on a singularly economical scale. The ident receives of annual salary £5625, the vice- ident £1125, and the secretary of state the same. of seven ambassadors is paid £2925. In 1837, general expenses were summed up as follow :—

	dollars.
ist, foreign intercourse, and miscellaneous, -	3,241,288
ary service, including fortifications, Indian ties, militia, improvements of harbours and rs; constructing roads and building mee- s, &c., - - - - - - -	11,417,774
l service, including expeditions, &c., - - -	6,622,020
st debt, - - - - - - - -	8,309
expenses of general government, - - -	31,315,407

he annual charge of the public debt is to be deducted the above sum, as the whole has now been very ly discharged. But in estimating the whole cost he government, it is necessary also to take into unt the sums required for the expenses of the diffe- states. We do not find any direct notice of the unt of these ; but as Captain Hall states that each on pays to the state government 3s., and to the ral government about 9s. 4½d. per annum, this portion would make the amount of expenses of the rent states about £2,087,029 ; and the whole cost overnment is therefore £7,722,009, amounting, rding to Captain Hall's estimate, to about 12s. 4½d. ach person. The national debt having been now ly paid off, the yearly sum paid in taxes, by each on, may be estimated at 8s. The only taxes are s on articles imported from foreign places, none ever being levied on the manufactures or produce he country itself ; and there are no direct taxes, the house or window taxes in this country. Part he revenue is derived from the sale of public lands ; this amounted in 1828 to £290,821.

ARMY AND NAVY.

he regular army of the United States amounts to ards of twelve thousand men : it consists of 735 missioned officers, and 11,804 non-commissioned ers and privates ; in all, 12,539 men. The militia timated at 1,350,895 men. In this body the men ire a certain knowledge of military exercises, but nit very little to subordination.

here is a military academy for educating young as officers ; the number under tuition is limited to ; and the instruction given is well fitted for train- their minds to knowledge and gentlemanly feelings : course consists of natural and experimental philo- y, mathematics, engineering, ethics, drawing, and usual military exercises. The young men educated are received into the army as cadets, and their notion is afterwards regulated strictly by seniority, ept in extraordinary cases.

he navy consists of 8 ships of the line, and 3 rs building ; 10 frigates of 44 guns, 2 of 36 guns, 5 building ; 29 sloops of war and smaller vessels, 1 armed steam-ship. The number of captains is 55 ; manders 54 ; and lieutenants 285. There are seven y-yards, of which the principal are on Long Island, r New York, at Philadelphia, and at Washington. ent events may have caused an alteration in this mary of the military and naval force.

Notwithstanding the free genius of the American constitution, and the little attention paid to wealth or difference of rank in common life, discipline is enforced with great strictness in the naval service, and with the more jealousy, perhaps, because there is always a danger of the seamen and inferior officers falling into the independent habits of their countrymen, which would be inconsistent with the authority of a commander at sea. Captain Hall tells a story of a young officer who announced his intention of appealing to the people on having been reprimanded by his captain. This being reported at head-quarters, an order came down to say, that the officer was perfectly at liberty to appeal as he proposed; and in order that he might do so without inconvenience, his discharge from the navy was enclosed. Great care is taken in the selection of persons wishing to enter the naval service; and these gentlemen are also exposed, afterwards, to frequent and rigorous examinations, by which means incompetent persons are excluded.

The ships of the American navy are generally well built, and good sailers: they are constructed in great part of a wood called the *live oak*, or *evergreen oak*, which grows in the salt marshes of Florida, and which is almost incorruptible. Large plantations of this valuable tree are formed, and carefully attended to by the government, the only instance in which forest trees are at all cared for in America.

MANUFACTURES.

The vast extent of culturable and prolific land in the United States, and the constant demand for large supplies for food, forms a reason why the nation should resort more to agriculture than manufacturing industry as a staple employment. The Americans, nevertheless, from a strong desire to be independent of foreign countries for a supply of articles of clothing, have thrown themselves energetically into a course of manufacturing, in relation both to soft and hard goods. Doubtless, they could be supplied with the articles cheaper from England than they could make them; but this seems a matter of indifference, and as the English think fit to exclude American grain from their market, the Americans in return exclude English goods. At present, they are engaged in a kind of rivalry with Britain, and it is certain that they are fast overtaking it, both in the excellence and cheapness of their products.

The manufactures which are followed with most advantage in America, and without fear of English rivalry, are those which produce articles too bulky or too heavy, in proportion to their value, to bear the expense of a long carriage, or of which the materials are found in the country, and can be wrought up there at less expense than by carrying them to cheaper tradesmen at a distance. Some of these branches may be mentioned—such as the making of soap, candles, and hats; tanning and working in leather, particularly bulky articles; building of carriages; making of all kinds of agricultural implements; carpentry, sawing, and turning of most descriptions; building of ships and steam-boats; constructing and putting up of mill-work and machinery; distilling; the employments of goldsmiths, tinsmiths, and printers. There are several businesses, however, whose prospects depend chiefly on prohibiting the cheaper manufactures of England, and which of course are liable to be deranged by any alteration in the tariff laws: these are the making of glass and earthenware; spinning and weaving most kinds of cotton goods; making of woollens, carpets, &c.; most of the finer kinds of hardware, iron, steel, and brass; hempen goods and silk goods.

Within the last few years the manufacture of cotton has been conducted on a great scale, by means of factories on the same plan as those in England. The cotton manufacture was introduced only in 1790, and in 1832 it was found that the number of mills in twelve states was 795, of spindles 1,246,503, of power looms 33,506; of males employed in the manufacture 18,539, females 38,927—total employed, 57,466. The amount of capital now invested in this thriving branch of tr mated at 45,000,000 dollars, equal to £9,375,0 being about a fourth part of the capital inv cotton manufacture in Great Britain. By the cotton cheaper than can be done in E Americans have an important advantage; ever, are higher. The principal cotton ma districts are in Massachusetts, Maine, and on the coast. The chief seat of the man Lowell, in Massachusetts, and it may be Manchester of America. Besides containi a dozen factories for cotton and woollen fab possesses large machine-making establishm employ many hundreds of workmen. All th ments in mechanism in England speedily way to this spot.

Household manufactures of woollen, linen, are made to a great extent. Many families s and make up their own clothing, sheeting, &c. They purchase cotton, and mix it up i with their linen and woollen stuffs; blank coverlids, stockings, mits, &c., are made ch family. These are perhaps neither so fine n expeditiously as those of regular tradesmen are produced for domestic use at times wh no other employment, and in this manner n to cost nothing except the material of whic made. It is supposed that nearly two-thi domestic clothing is so made in country pla families, as in Canada, having a loom in the is the same with soap, candles, and maple-s which are manufactured by the farmers at h articles made by families in the state of Ne their own use, were, in 1831, reckoned at in value. Attempts have recently been m great success, to introduce the manufacture mulberry-tree grows spontaneously in the mi and the light easy labour which the collecti silk requires, would afford employment to and females, enabling them to add to the their families, when they could not otherwi to do any thing.

The native American manufactures, limit are in some respects, are sufficient to give em to every one who wishes to work; and ther continual call for new hands. Capital also f dant remuneration in the existing state of that there seems to be no necessity for the troubling themselves to establish new ma all their spare hands and spare money bei occupied to advantage. English workmen skilful and steady, are almost certain of findi ment with good wages, in one or other of the turing towns; but it is here necessary to stat American manufacturers make serious against operatives from British factories, w describe as arrogant, intemperate, and un habits. The chief ground of complaint is th perance, a circumstance partly arising from t ness and abundance of intoxicating liquors, bu a want of due personal control. We mentio warning; for no intemperately disposed work think of leaving their employment in Brita an asylum in American factories.

In the southern states there is little manuf the inhabitants there depend on the north or on foreign countries for their supplies, exports are cotton, sugar, and other raw mat

COMMERCE.

The wealthiest class in the United States rally the merchants of large sea-port towns. C may be considered as forming the aristocra country, and is regarded every where as highl able. Young people are educated for it with care as for the army, or for any of the lea fessions; and they acquire a knowledge of the of the foreign countries with which they pro connected, their modes of transacting busi

exports. This excess of the imports over the has continued since the year 1831, but the e is now considerably less than it was at that t appears that these sums form about half the of the British foreign trade. The American however, is nearly equal in tonnage to that of This apparent inconsistency is accounted for ays: first, a great deal of the trade to Britain d on in American bottoms, and not equally in the two countries; and, secondly, there is a antity of tonnage employed by the Americans asting or internal trade of the country than in Britain. It is, in fact, the traffic between rent parts of the Union, which gives its chief to American commerce.

mmense number of navigable rivers which run the country in every direction, and discharge es into the ocean or the lakes, afford the means at internal trade. These facilities have been d at many important points by canals, con- the different rivers at points where they ap- ach other, or where they flow away in opposite s from sources lying in the same neighbourhood. the southern and eastern states there is a con- erchange of commodities along the coast, and trade goes on from the western states to the the Ohio and its branches, down the Missis- New Orleans is the great entrepôt for the goods tter branch of internal commerce. The north- states furnish rum, molasses, cordials, dried ropean goods of all descriptions, and articles of ne, quaintly styled *notions*; and they take in orn, grain, cotton, and tobacco, from the south; om the western states are received hams, beef, r, &c., either for use or for exportation to the dies and the other parts of Southern America. the extent to which this traffic is carried, we ition that there are two hundred large steam- the Mississippi, making the voyage up and twenty-four days. The cargo of one of these as follows:—501 barrels of pork, 9 hogsheads , 2138 kegs of lard, 3147 barrels of flour, 30 gin, 92 barrels beef, 50 boxes merchandise, 32 porter, 224 barrels eggs, 50 horses, 32 cabin rs, 42 deck do., 31 way do.; and this was the rgo every trip. The traffic from north to south e coast is greater than might be inferred, even a specimen of internal trade by the rivers; the productions of the northern and southern on the sea-coast are as different from each those inland, while the states in that part of try have been longer and more densely peo- his active intercourse by rivers, canals, rail- nd sea-coast, increases the value of land and ry every where: the produce of the agricultural s can always be sent easily to the towns, and manufacturing places to those which are more ely agricultural. The United States have too mmenced industrial operations, to possess either lth or available resources of such an old-settled strious country as England, and therefore both ency and means of defence are upon a compa- meagre scale. The bulk of the money, for in- employed on great public works, and borrowed different states, has been lent by British capital- the stock of the United States Bank, five-sevenths erstood to belong to England. So stupendous, r, are the natural resources of the States, and ly may they be developed, that with peace, and owing those pursuits of industry which are iate to the country, the nation at large cannot long a debtor to foreign powers.

CANALS, RAILWAYS, AND PUBLIC WORKS.

n America was first settled, the people chose the vicinity of the sea or navigable rivers, so ve the means of free communication to all parts r; and lands even of inferior quality were found alumble in such districts than richer soils in

are now hardly to be equalled in the world, and these channels have opened the tide of population and prosperity into inland districts and rich lands, which must otherwise have lain waste and lost, except to a few slovenly and ignorant persons. One of the states alone (Pennsylvania) has, since 1826, devoted no less than £5,800,000 to this object. New York has been even more liberal; and there is no part of the country (always excepting the slave states, which in this respect, as in all others, are greatly behind) where such means are not taken to afford the occupiers of land means of bringing their produce to the market of cities. This is a matter which very nearly concerns the settler every where; because, however good the soil of his farm, or however unremitting his own industry may be, every advantage would be thrown away, if he could not get the produce disposed of. Some of the settlers in Canada, at the head of Lake Erie, were so badly off in this respect, till the opening of the Erie canal, that their surplus wheat and cattle were worth nothing: money was not given for farm-produce in that quarter. Wherever there is a good canal or navigable river, on the other hand, the prices of farm-produce rise, and land which was unsaleable becomes in request, and is covered with a throng of settlers from Europe, or of the restless speculators of America.

The Erie canal was planned by an American patriot, Mr De Witt Clinton, and was carried into effect at the expense of the state of New York. It extends three hundred and sixty miles along a rich and fertile country, which had formerly no communication with markets, but which can now send its produce to the sea in two directions. It is forty feet wide at top, twenty-eight at bottom, and four feet deep. It was finished in five years, at an expense of 9,027,456 dollars. The waters of Lake Champlain are connected with the Erie canal by another sixty-three miles long, which was executed at an expense of 1,179,871 dollars. The amount of tolls collected on these canals in 1822 was 44,486 dollars, and in 1834 this had increased to 1,313,155 dollars.

Houses, villages, and towns, are starting up along the whole line of the Erie canal, with unexampled rapidity. Lockport, for example, is a place where the canal is carried by locks up a steep rock of seventy feet. This spot has been suddenly transformed from a wilderness into a thriving village of two thousand inhabitants. Rochester is another example of the benefits the canal has conferred on the country: at that place there was abundance of most fertile land, and there were also certain falls on the river Genessee, which were admirably adapted for giving water-power to mills and other machinery; but all these advantages existed to little purpose without good roads and markets. The opening of the canal has supplied these; and the consequence has been, that Rochester has all at once started up from a desert into a populous city, and presents, says Mr Fergusson, a remarkable instance of what may be done in the way of transition, exhibiting in its streets a perfect sample of the progress from stumps to steeples. It is not long ago since its most crowded streets were a forest. *The first settlers* cut down the trees, leaving *the stumps standing till* they had more leisure; and

a canal stretches from the Delaware to t
from the Delaware to the Chesapeake; a

are formed on the flat region lying around them.
incipal lakes are four in number, and are called
ning from the eastward) Lakes Ontario, Erie,
, Michigan, and Superior; the navigation from
ntario to Lake Erie is interrupted by the Falls
ara, where that river (the same which is called
Lawrence after it quits the lakes) is precipitated
rock of 160 feet high. From Erie to Huron,
of large size pass uninterrupted, but the commu-
n is impeded in the channel which connects Lakes
gan and Superior with Lake Huron, by the straits
dary. At Niagara, a canal, called the Welland
has been formed by the British government on
nada side of the river, which enables vessels to
om Ontario to Erie without impediment; and the
ll no doubt be performed by one or other of the
ments for the straits of St Mary, whenever the
ase upon these more remote lakes shall justify
pense of such an undertaking. The whole chain
e inland seas will then be navigable from one end
other; and as their shores are all of great fertil-
e region lying around them may be expected at
uture time to be one of the busiest and richest
globe. At present, as they extend along the
rn limits of the United States, they afford to that
boundary nearly the same commercial advan-
s those possessed by a sea-coast, and give a sti-
mulus to the industry of all the districts con-
with them. The following is a summary of par-
s connected with the extent, depth, &c., of the

	Length. Miles.	Width. Miles.	Depth. Feet.	Elevation above the Sea.—Feet.
,	180	40	500	231
	270	80	200	565½

gan,	400	50	unknown.	613
or,	400	100	900	641

e of the navigable rivers of the United States
o the lakes, and there is no river that flows out
n over which that country has command, so that
d appear that the advantages it can derive from
are but limited. To remedy this inconvenience,
the Americans soon perceived and regretted, they
ed canals from the most of their inland districts
upper portion of the lakes; while from their
shore (or that which is next the sea) they have
ted others, to give them an outlet to the ocean
their own territory. The navigation is thus
ed complete, from the shores of the sea at New
by a canal, to Lake Erie; thence to Huron and
gan; and from thence by other canals to the in-
ates of the west.

igable Rivers.—The navigable rivers on the
n side of America are numerous and important.
ay first mention the Connecticut, a large stream
; into the Atlantic near the north-east end of
Island: the Hudson, a river navigable for steam-
of the largest class for one hundred and sixty
above its mouth, and the channel which has en-
New York to extend its commerce by a canal to
kes: the Delaware, flowing past Philadelphia,
fording communication by itself or its tributaries
country three hundred miles in length, and of
equal breadth: the Susquehannah, the Potomac,
mes River, and others flowing into the Bay of
peake, which, by the help of canals, afford en-
to vessels of one kind or other into the deepest
s and recesses of the eastern country. Southward
e Roanoke, flowing into Albemarle Sound, and
mlico River, affording channels for the commerce
rth Carolina; while South Carolina and Georgia
nnelled in the most complete manner (if we may

use the expression) by the rivers Pedee, Santee, Savannah, Ogeechee, Alatamaha, &c.; and East Florida enjoys the same convenience in the River St John's and its branches.

But the eastern rivers, useful as they are (and they have certainly as yet been the chief seats of commerce in the country), are by the Americans themselves entirely lost sight of in the enthusiasm of their admiration for the immense streams which water the western and inland states. These great rivers are certainly not to be equalled in any other country, at least in any country which has had such skill, or such a form of government, as have enabled its people to turn the commercial facilities of their inland waters to proper advantage. The rivers to which we allude are the Mississippi, and the large tributaries which arrive from the east and west to fall into the channel of that great stream.

The number of steam-boats on the western rivers in 1834 was about 230, measuring 39,000 tons. Besides these, there are 4000 flat-bottomed and keel boats, with a tonnage amounting to 160,000. Only a few of these vessels, however, are fit to go to sea, being only suited for river navigation.

MINERALS.

There is a great variety of useful minerals distributed through different parts of the states. Coal may be mentioned among the first: it exists through all the country, lying north of a line drawn from Philadelphia to the mouth of the Ohio, and is particularly abundant on the upper waters of the Susquehannah, as well as on the Alleghany and the Monongahela. At Pittsburg there is a hill principally composed of coal, and it is found at many places in this district within a few feet of the surface. There are extensive coal-mines also on the Roanoke and Appomatox, in Virginia.

The country on the Ohio is particularly rich in mineral productions. The whole district is bottomed on limestone, on which rests the wide and valuable coal formation mentioned above, extending from the head waters of the Ohio, in Pennsylvania, to the river Tombigbee. Iron ore is found abundantly in the same district, principally towards the upper part of the Ohio; bog ore is found in the valleys of the Alleghany chain; and various kinds of ores, of the same metal, are met with in the New England states: at one place, carbonate of iron is found, which, on being reduced, produces steel, and is called *steel ore*. Black lead, in beds of from five to six feet wide, traverses the states of New York, Jersey, Virginia, Carolina, &c. Copper ore is found in Virginia, in Connecticut, and in New Jersey: it exists also in the neighbourhood of the lakes; and a piece of pure malleable copper, weighing three pounds, was found in Illinois.

Gold mines have been traced extending through a large tract of country in the western parts of Virginia, North and South Carolina, and Georgia: they are wrought to a considerable extent, 20,000 men being employed at the different workings: the miners, who are people of all countries, say that the produce is richer than that of any other mines on the globe: one piece of pure gold was found weighing twenty-eight pounds. The annual produce is about one million sterling; but we have not heard what proportion of this is expended in the work, or what actual profit has been realised. One singular fact is remarked concerning these mines, which is, the indubitable evidences found that they have been wrought at some period before America was known to the Europeans. Many pieces of machinery which were used for this purpose have been discovered in the workings, among which were several crucibles of earthenware, which are far better than those now in use.

Silver and its ores are not of frequent or extensive occurrence. Mercury has been found native in Kentucky, but it occurs plentifully in the ore as bituminous cinnabar, through the Ohio and Michigan territory. It is found in the soil as a black or red sand, sometimes as a fine red powder, and at other times in iron clay. There are lead mines of vast extent on the Missouri; they are said to occupy a surface hundred miles in length, and two hundred in One miner will raise about two thousand pe day, which sell for forty-five dollars, and yie hundred pounds of pure lead.

Epsom salts, Glauber salts, and nitre, are Ohio and Indiana; the two latter in caves, th in a thin layer on rocky surfaces. Salt, whic tries far removed from the sea is an article expense, is produced from salt springs, or fro in different parts of the western country. waters of valuable medicinal qualities occur places; the springs principally frequented ar Saratoga, in New England. Oil of vitriol, or acid, is got almost pure from the earth, in near the town of Byron. It oozes out from a low hummock, and may be collected by digg in the ground. There are several places whe mable gas issues from the earth: one is a s called Sodom, the bottom of which is formed green slate, the sides of white shell-marl, and of black mould; the water is uncommonly tra so that the basin looks like an immense porcel the water is of the quality of that of Harrow gas issues from it abundantly, and, when kindl along the surface with a bright red flame by

GEOLOGICAL PECULIARITIES.

In examining the geological structure of rican continent, some singularities have been which are believed not to correspond with th formed in Europe on this subject. We shal a few of those which appear to be most in There is no chalk found any where in the state is there any roestone (or oolite, as it is calle logists), though the localities where both mig pected are sufficiently marked. Mr Macla that some shells of the recent alluvial form New Jersey are identical with species found condary rocks. There have been discovered limestone of the elder secondary formation, t of human feet; the marks are those of a ma nary size standing erect, with his heels draw his toes turned outward; the toes are muc and the feet flattened, like those of people t tomed to shoes; the impressions are strikingl exhibiting every muscular swell and depres accuracy. Every thing seems to warrant th sion, that these marks were made at a time rock was soft, and received them by pressu geology dates at a period very long indeed general flood. They were examined by Gove and Mr Schoolcraft, at St Louis and Hercul the Mississippi, and they exist also at the land mountains, always in the same kind of Other singular facts (unconnected, however, above) have been observed in this district. away plains, on the Ohio, a human skeleton seventeen feet below the surface, in a bed and shells deposited by water, and having ni earth over them. At Cincinnati, in digging arrow-head was found ninety feet below the and in Illinois, fragments of antique pottery of coarse earthenware have been found at eighty feet below ground. In forming the E the workmen, when digging this ridge of gra several hundred living shellfish at a depth of feet. They were chiefly of two kinds of *m* water mussel, of which several species exist in one, called *smurstin*, is used for food in Zet another is eaten about Cork, where it is cal *loons*; we do not know if the species which out of the gravel are found among the prese can shellfish. *Living toads* have been found in as here, in solid rock, of what has been called stone-grit.

PECULIARITIES OF DIFFERENT DISTRICTS

America is generally considered and spoken

untry, its people as forming a single nation, and the marks which are made with regard to one part of it e supposed to be equally applicable to all. No idea, wever, can be more fallacious. The region which term the United States is composed of sections of untry as remote from each other as London is from nstantinople, or Madrid from Berlin: they lie under ferent climates, and the different circumstances under hich their inhabitants are placed form in each a totally ferent set of manners. The English language is mmon to all, and they all profess the Christian reli-on; but in most other respects the difference between nm is as great as between any two European nations. he great divisions under which the country ought to viewed are the north-eastern or New England states, which for the present may be included Pennsylvania; 2, The southern or slave states, to which section also may refer Kentucky and Tenessee; and, 3d, The w states of the west, which are in progress of settle-ent. The manners of the New England states are rmed on the model of those of our own country, and ere are few circumstances in the nature of the climate hich tend to produce any material alteration; it is mong them only that due provision is made for the ucation of the people or for religious instruction. he productions of the soil—the modes of agriculture —the arts and occupations to which these give rise— e alternations of season—and many other things, have ll a resemblance to those of our own country. They ltivate wheat and the other European grains; their rden vegetables, potatoes, turnips, carrots, cabbages, c., are the same as ours; they employ the same do-estic animals; and they use, of course, the same agri-ltural implements, the same grist-mills, &c., requiring e the same tradesmen to prepare and work them.

Even in these great divisions which we have pointed t, there are portions which differ exceedingly from ch other. New Orleans, for instance, which belongs the slave states, has a completely different set of anners from Charleston in Virginia. The former is a y of immense trade, situated at the mouth of the eat river Mississippi; it contains a mixed population f blacks of all shades, and of white men from every tion in Europe. Its streets are crowded and speckled th people of every colour; its quays with ships of ery country; and its wharfs are loaded with bales of ods from all quarters of the earth, some coming from rope or from China, to be carried for three thousand les up the inland rivers of America; others sent wn these rivers some months' voyage, to be carried the West Indies or the Mediterranean. The air of e place is unwholesome, and it is a mart where peo-e hurry to make money before they be overtaken with kness and death. Such are the influences under which e manners and character of the people of New Orleans re formed. Charleston, on the other hand, is the pital of a wealthy agricultural state; the pursuits of e people are not decidedly commercial; the town is e resort of numerous country gentlemen, who pride mselves rather on the oldness and respectability of eir families, and the extent of their property, than n the activity of their business habits. The gentry trive to keep up, between themselves and their slaves, n exterior resemblance to the feudal relations of Europe; coats of arms are fashionable, as are liveries r servants: there is a general air of elegance and plendour in the buildings of the town: some of the ouses "are real palazzos, surrounded with orange ees, magnolias, and other trees of an almost tropical limate." There is much taste for the fine arts among e higher classes, and among the lower an absence of ll that bustle and variety of language and dress which ark a great commercial city. It is obvious, therefore, at the manners of these two places can have very ttle in common.

If we glance at the northern states, we shall find a difference of a similar kind existing between New York and Philadelphia. The former city is the great thoroughfare of all emigrants and commercial agents who arrive from Europe; the people passing through it daily are sometimes estimated at 15,000 or 20,000; it lies at a central point, having communication, by rivers, canals, and railroads, with the whole northern parts of the American continent. Grain, provisions, lumber, and manufactures, are brought from countries a thousand miles inland, for exportation, or for the use of places along the coast which have not the same facility of conveyance. People arriving there are secure of finding a passage to every other city inland or coast-ways; hence the streets and quays are constantly crowded with travellers and their luggage. The extent of its commercial transactions gives a facility to those who wish to engage in any kind of speculation, because here they can always learn the prices or the demand for every article of American produce; hence there is a restlessness, bustle, and continual spirit of change among its population, or a great part of it, which it would be vain to seek elsewhere in Europe or in America. Philadelphia, on the other hand, though also a place of very extensive commerce, has fewer channels of communication with the distant inland countries, and has of course a smaller variety of produce either raw or manufactured: hence there is less speculation; business proceeds with more steadiness, but less apparent bustle; there is in the streets an air of quiet regularity, where every one seems to go easily and leisurely about his business: and the transit of strangers through the place is but inconsiderable. The prevailing religion, which is Quakerism, has also a manifest influence in producing these effects. The influence of circumstances upon the manners of a people is nowhere more remarkable than it is here in the case of the negroes. Slavery is not permitted in this state; and the inhabitants do not countenance in all its severity that feeling of contempt with which black people are regarded in other parts of the Union; hence the Africans reside here in freedom and comfort, while they see their countrymen, a few miles to the southward, poor degraded slaves; and they are generally in consequence a contented, cheerful, and industrious caste.

Again, if we look at the western states, we shall find that, though there is a certain uniformity of manners over the whole, they are here also differently modified, according to circumstances. Pittsburg, for instance, with the neighbouring towns, Wheeling and Steubenville, are in the centre of a country which is rich in various kinds of minerals—coal, iron, lime, &c.; they are therefore filled with a manufacturing population, and the pursuits, appearance, and manners of their inhabitants, differ from those of the country around them, as those of Birmingham may be supposed to do from other places in the centre of England. The town of Cincinnati, again, which is situated on the Ohio, as these places also are, is a great inland depôt for merchandise to be exported or imported. Its inhabitants are merchants, attendants in counting-houses and ware-rooms, owners of river steam-boats, and a population attracted by the general trade of the place, while there is also a large number who are occupied in the very peculiar business of killing and preserving for exportation the immense quantities of live-stock reared in the country.

CLIMATE, SOIL, AND NATURAL PRODUCTIONS.

The state of Maine, which is the farthest north of the Union, reaches to latitude 48°: Florida, on the south, extends to within 25° of the equator. Between these two points there is a great variety of climate, and the differences of temperature are increased by the flat or sheltered situation of some districts, and the mountainous features of others. The New England states and Pennsylvania, lying between 40° and 48° north, approach nearest to the climate of England; but, owing to causes which are not yet perfectly understood, the whole Atlantic coast is warmer in summer and colder in winter by about 10 degrees, than the same latitudes in Europe. Some of the plants of this country, such as the holly, and the common *whin* or furze, when transplanted

thither, fade equally under the heats of summer and the frosts of the cold season, and cannot be preserved except in greenhouses. In winter the rivers are frozen, so as to bear horses and waggons. The air is in general drier than in this country, and wet showery weather much less frequent; so that farm work is conducted with more regularity and more security than with us. Winter does not set in till the middle of December; after which frosts continue with more or less severity till March, with frequent and great changes from mild weather to intense cold. In April the season becomes again fine, sunny, and dry.

In the states south of the Potomac, the climate is much warmer; the winters, which indeed are hardly to be called winters in our sense of the word, are short and mild, frost being little felt except during the night. The heat of the warm season is like that of tropical countries; but this is felt chiefly on the sea-coast, which is in general low, flat, and far from healthy. The inland parts being more elevated and hilly, the climate there is more temperate. The whole coast from north to south is subject to tremendous hurricanes, which sometimes do much mischief.

The climate of the western states, forming what is called the Basin of the Ohio, is different both from that of New England and from the southern districts in the same latitudes. The *average temperature of the year* is nearly the same at corresponding points on both; but there are fewer inequalities in the west, neither the heat nor cold reaching the same extremes. The thermometer seldom falls more than ten or twelve degrees below the freezing-point. Frost does not become permanent till near the close of December, when standing water and small rills are frozen from three to fifteen days. Many plants, such as the cotton, the catalpa, sassafras, the Illinois nut, flourish in the western states, in latitudes where they would not thrive on the sea-coast. The air is more moist, fogs and heavy dews more common.

Soil.—That portion of the New England states which lies east of the river Hudson, is broken and hilly; the soil in general thin, unproductive, and better adapted for pasture than tillage. From New York, all along the sea-coast southward to the Mississippi, there is a tract of flat sandy soil extending inland from thirty to one hundred miles; it produces nothing but shrubs and pine-trees, except on the banks of rivers and marshy places, where rice is grown. Backward from this line to the foot of the Alleghany Mountains, there is a tract of carse land of variable breadth, but of great fertility. The Alleghanies themselves are not cultivated, but the valleys between their ridges are rich and useful land. The district inland from these is the Basin of the Mississippi, a region of vast extent; it is generally bottomed on limestone, well watered, and inexhaustibly productive.

Agricultural Productions.—Oats, rye, and barley, are raised in all the northern states, and also in the hilly districts of the south. Of barley, two crops in a season are obtained in favourable situations. Maize is common to every part of the Union, but thrives best in the middle states; it is a vegetable adapted to a greater variety of soil and climate than wheat, and yields a much larger produce. The sugar maple grows every where, but thrives best in the good maize districts. Wheat is also cultivated through the whole Union; but it is only a profitable crop to the north of the Potomac, or in the hilly districts of the south; in these situations it yields large returns, and of excellent quality; in the [illegible] warm districts it is not cultivated; these are more [illegible]rable to the rice crop. In general, it is remarked [illegible]e late wheat countries are favourable to the [illegible]an constitution, and that in rice countries, which [illegible]m and moist, the African population has a great [illegible] in respect to health and longevity over whites. [illegible]ltivation of tobacco begins in Maryland, in [illegible]9°; it is raised to a greater extent in that [illegible]in Virginia than in any others of the Union; [illegible]ves also in all the western states. Cotton does not succeed well farther north than the la[illegible] 37°, though some of the districts raise it for [illegible] use; it forms the staple of all the districts sou[illegible] river Roanoke. The best kinds grow in South [illegible] and Georgia, in dry situations, upon the sea-co[illegible] cultivation of rice occupies nearly the same [illegible] that of cotton; it is a very unhealthy occupatio[illegible] slaves who are engaged in it. The climate [illegible] favourable to sugar does not extend beyond the[illegible] of 32°; it is raised in the states chiefly for [illegible] use, and is not an article of export to any exte[illegible] crop is rather precarious, from the frosts whic[illegible] times occur even in the most southerly districts. [illegible] has been tried in America, but could not co[illegible] competition with that of Bengal.

The vine grows spontaneously in most of the [illegible] and western states, and is cultivated as a fru[illegible] Philadelphia. The mulberry tree, hops, and h[illegible] succeed well in the middle and western states.

The timber-trees of the states are of numero[illegible] and many of them of the best quality. Th[illegible] twenty-six kinds of oak, of which eleven or[illegible] species are in request; the best for common [illegible] is the *white oak*, a tree which is found plentifu[illegible] the whole country: the *live oak* grows in marsh[illegible] near the sea, and has a hard, heavy, and durable [illegible] much used for ship-building. There are eighte[illegible] of pine, cedar, and larch; seven kinds of map[illegible] or four of which furnish sugar—the best is ca[illegible] sugar maple; ten kinds of walnut trees; four [illegible] birch, the bark of one of which furnishes the [illegible] with canoes; six kinds of ash (the ash of this [illegible] is not of the number); besides many other t[illegible] very useful qualities. There are one hundred an[illegible] kinds which rise to a height of more than thir[illegible] while in France there are only thirty-seven of t[illegible] The flowering shrubs, *kalmia* and *rhododendron*[illegible] are cultivated here with so much attention f[illegible] splendid flowers, grow wild on the sides of the A[illegible] hills, to the height of fifteen or twenty feet.

Even in the most thickly peopled states, th[illegible] still remaining large tracts of uncleared woo[illegible] which give the country a wild appearance, an[illegible] an aspect on the whole very different from an[illegible] seen in Europe, where forests have long b[illegible] valuable to be allowed to remain uncut.

RATES OF PROFIT, WAGES, AND STYLE OF LIVI[illegible]

There is abundance of fertile land in the [illegible] States, which needs only to be broken up and [illegible] of woods to yield large returns for a slight [illegible] There are none of those obstacles to the cultiv[illegible] solitary districts which exist in the lawless or[illegible] proved condition of some other countries. P[illegible] is secure every where, and there is hardly a[illegible] however remote, which has not ready commun[illegible] by rivers, canals, or roads, with one or other [illegible] large cities. Hence, fertile lands which are [illegible] access are to be found by every one who is at a [illegible] employment, or who thinks his present occupati[illegible] profitable than he would wish. On such soi[illegible] accumulation of capital in agriculture is much[illegible] rapid than has ever been exhibited in any other [illegible] The valuations of 1799 and 1814 furnish inte[illegible] information on this head. From these it appear[illegible] in the fifteen years between these periods, the v[illegible] lands and houses (not reckoning slaves) in the [illegible] teen states, had, on an average, increased one hu[illegible] and sixty per cent., or from a hundred to two hu[illegible] and sixty. The rate of increase for the whole is[illegible] 6½ per cent., and the original capital is doubled in[illegible] eleven years. At this rate, capital accumulates[illegible] than twice as fast as population; or in other wor[illegible] increase of the people is always met by a double in[illegible] of the means for employing and maintaining [illegible] These remarks are derived from the condition [illegible] agricultural population; but they apply equally [illegible] whole, the rate of profit being the same in all o[illegible] tions. No man will submit to take small wages,

former statement. The number of foreigners not naturalised who were residing in the states in 1830 was 1,587; and as these persons cannot be naturalised till they have been five years in the country, this amount, with a little deduction, may represent the arrivals during the last five years, which will therefore be about a thousand per annum.

The census for 1830 gives the number of persons who have attained the age of one hundred and upwards, as follows:—

White men above one hundred, - -	297
White women, - - - - - -	234
Black people—men, - - - -	1000
... women, - - -	1011
	2541

The proportion of black people who live to a great age appears therefore to be much higher than that of the whites. This advantage the African race seem to possess chiefly in the southern districts. In ten of the states south of the Ohio and Potomac, the whole number of white inhabitants was five and a half millions, the number of blacks one million and a half (nearly); but of the former only three hundred are above one hundred years of age, while of the latter there are 730—a circumstance which shows that the climate of the south is better fitted for the negro constitution than for that of white people. Of the latter, only one in nineteen thousand arrive at the age of one hundred; while of the Africans one in every nine hundred reaches that age. On the subject of longevity we may mention, that, in August 1817, within a circle of twelve miles in diameter, in North Carolina, there were living sixteen persons between eighty and ninety years of age, twelve from seventy to eighty, and twelve from sixty to seventy. A child was lately born there whose father was eighty-four and mother fifty-seven years at the time of birth (*Warden's United States—Walsh's Register*). In Cumberland county (Virginia), seven persons died between the ages of ninety and one hundred and twelve years, within a short time of each other. In South Carolina it is remarked, that all who could be found above eighty (1808) were emigrants from Europe, and living in the upper hilly country.

THE COLOURED POPULATION.

Slaves.—The states which continue to support slavery are those which lie south of Pennsylvania and the river Ohio, with the new districts to the westward of the Mississippi; in all the others it is abolished. The whole number of slaves in 1830 was two millions. The condition of these poor people is every where very low; the field slaves are fed, lodged, and attended to, exactly on the same principle as that on which farmers in this country take care of their oxen and horses; a planter is sorry to see them dying or diseased, because he loses their labour, but they meet with no farther regard. It is frequently profitable to cultivate rice in very marshy grounds, or in fields artificially overflowed, where the negroes must work up to their knees in water in the heat of the day. Numbers of them take sick and die in this unhealthy occupation; but the planter only calculates whether the profits of his crops will pay for the number of new negroes which he is obliged to buy; he never thinks of the distress of these poor people, and even takes credit to himself in being liberal in sacrificing his blacks, in order to keep those rich grounds in cultivation which otherwise must be lost to the country. Mr Stuart of Dunearn mentions, that even where the slaves were well fed and attended to (as it is the interest of every proprietor to do with his cattle), he found them, in respect to knowledge and feeling, little removed from brutes, while all declared themselves unhappy and miserable in their situation. When their tasks are found deficient, they are whipped, put in the stocks, or forced to wear irons. One person was in the habit of punishing his slaves by fixing them down in coffins, and some of them had died under that treat-

ment. The cruel owner might have been punished by law had there been sufficient evidence of the facts; but as he took care to have no one present but slaves, whose testimony is not admitted in the courts, nothing could be done.

The gangs of slaves on large estates are in general tolerably well fed and clothed; but there is a numerous class of slaves belonging to very poor, and often very improvident, white people, and these are exceedingly wretched, toiling hard, with little subsistence and the harshest treatment. In all cases, the slaves live together with little more feeling of the decencies of life than the brutes that perish. Even when they are employed as waiters in the large inns and hotels of cities, they are not furnished with beds, all lying like dogs in the passages of the house. There are laws by which every one who shall teach a slave to read, or permit him to be taught, may be imprisoned for twelve months. The advantage of having labour performed by slaves, is to the proprietor very considerable: they are maintained at an annual expense of about thirty-five dollars each; while the interest on their original cost, at ten per cent., may be forty dollars; the amount is seventy-five dollars, or about £17 per annum. Now, the wages of a white labourer are here three times as great as in Europe, and cannot be reckoned at less than five hundred or six hundred dollars, from £120 to £150. It is no wonder, therefore, that the proprietors of slaves in America are jealous of any attempts to instruct or emancipate them.

Free Blacks and Coloured People.—From the black people having been first introduced into America as slaves, they are regarded every where with great contempt, whether free or in bondage. In the states where slavery remains in force, the free negroes or mulattos are treated with the greatest contumely; every impediment is thrown in the way of their obtaining education; and the senate of Virginia even voted that the increase of schools for coloured people was a nuisance which ought to be put down: by laws in the several states, any one who may instigate them to resent this ignominious treatment, or in any way to diminish the respect which is commanded to free people of colour for the whites, may be punished by fine and imprisonment. Clergymen in their pulpits, and judges on the bench, are not exempted from this regulation. But even in the free states, though laws of this kind are not in existence, people of colour are subjected to every mortification: they are not allowed to eat at the same table with white men, to attend at the same public meetings, or even to enter the same churches. From being thus always exhibited in a kind of degraded light among the more powerful class, they have not the same respect for themselves which they ought to entertain. Of the persons who are punished for crimes, a larger proportion are people of colour than whites. They have a greater difficulty in getting proper remuneration for their industry or talents than that favoured class; and their exertions are discouraged in all the higher lines of life. Numbers of them, however, notwithstanding all these difficulties, rise to great wealth, and live in a style of much elegance. They have churches and schools for themselves, with ministers and teachers of their own people. Great exertions are making by the Quakers, and other benevolent persons in the free states, to establish and maintain respectable schools for the education of black children. As the memory of their former slavery wears away, they will come to be regarded in a more favourable view. The whole number of free coloured persons in the states is about 300,000.

The Indians.—The number of Indians now remaining within the territory of the states, is estimated to be somewhere between 400,000 and 600,000; of these, about 75,000, consisting of tribes called Cherokees, Creeks, Chickasaws, and Choctaws, are in possession of tracts of land lying contiguous to each other in Georgia, Alabama, and Tenessee. There have been some disputes concerning their territory, and some of the adjoining states have used very despotic means to have them ejected from it: they still, however, re session; and as any violence done to them would excite much odium both in Europe an well-thinking people in the states, they are li to remain undisturbed. They have quite renou character of savages, and are all more or les gress towards civilisation; they cultivate whea pumpkins; rear cattle and horses; manufact oil, leather, &c. The tribe which has m greatest advances is the Cherokees, whose po in 1824, was 15,560; in 1810, it was 12,400, so are not falling off in number like the other They possess a fine, well-watered, and arable of five millions of acres; agriculture is well und apple and peach orchards are common; bu cheese are produced of good qualities: they ha good horses, and about 22,000 head of cattle. of them are good tradesmen, as blacksmiths, millers; and they have saw-mills, grist-mills, and other furniture of an improving communit have a newspaper edited by one of their own p their own language. Numerous and flouris lages are seen in every section of the country are remarkably clean and neat in their pers practise bathing universally. A young man the hand of a young Cherokee woman: she his offer, and gave as a principal reason that not clean in his appearance; that he did no Cherokees do, bathe himself in the river. T sider bathing and cleanliness in the light of virtue.

The Choctaws, Chickasaws, and Creeks, have so much noticed as the Cherokees; but they, in a satisfactory progress towards civilisation have good orchards and corn fields, and some are the owners of inns or hotels on the roads their country, which are found, we believe, to comfortable places of entertainment to tr There are a few books in the Choctaw langua the Creeks produce very neat articles of potte vases, &c., and pipe-heads of black marble ploughs, spinning-wheels, &c., are a further their thriving condition, and the growth of ec habits.

The Indians in the northern part of the st along the lakes, retain much more of the idle habits of their ancestors than the southern tri those of them who remain near the white set little superior in appearance or character to th of Europe. Reserves of land have been set them out of their former hunting grounds, and cases these have been entirely surrounded by t and settlements of the whites, the Indians still ing in their original patch of forest. In this st appear to be like animals of prey under confi their natural occupation is taken from them, seem to have no powers for any other. Their are found to be smaller upon every enumerati their idle, uncomfortable way of living, with t spect which is every where shown them by th tend greatly to prevent any spirit of union amo or any steps to prosperity. Some few of th settled into agricultural communities, and ha houses, churches, &c.; others have submitt time to the instruction of missionaries. Bu adds nothing to their respectability among th people, who prefer a good hunter to a good m they have seldom the steadiness to persevere.

Treaty stipulations, as they are called, ha entered into between the American governm most of the Indian tribes, for the removal of t from the east to the west side of the Mississipp has been partly carried into effect, and it seer that the Indians will soon be removed altogeth the States. In 1838, 25,139 Indians emigrated the Mississippi, and by this the American gov acquired 18,250,000 acres of land, for which 3,738,000 dollars in money or in lands.

"With regard to those Indians who refuse

re early with them than in this country; a circum-
nce which contributes to this practice of boarding.
young people, though they have always abundant
ployment and subsistence, cannot till after some time
umulate sufficient for furnishing a comfortable home.
e have Mr Cobbett's authority for stating that long
rtships receive no countenance from young ladies
America; females of every rank very quickly dis-
s a lover who requires time to make up his mind.
may be noticed here that women every where receive
greatest attention, both in their families and when
y have occasion to go abroad. Captain Hall, who
ms at one time to doubt concerning this circum-
nce, says in another, "it is a rule which we saw
iversally attended to in America, never to think how
n shall fare, till every female has been fully accom-
dated." As a proof that the same feeling exists
ong the working classes, we may mention, that in
ming establishments the females are never asked to
any work out of doors.

On American manners, Mr Shirreff, in his Tour in
rth America, has the following remarks. "On reach-
the United States, the plainness of the people's
nners appeared remarkable. In all classes there
s a total absence of grimace and corporeal token of
pect, with corresponding sounds of address, an ex-
ssion of obligation or thankfulness seldom being
rd. But on the other hand, vulgarity, rudeness, or
olence, is almost never met with in the humblest
lks of life. A general propriety of department and
ness of manner pervades the lower classes. In
nerica every individual seems possessed of self-re-
ct, and, in the intercourse of life, arrogance is seldom
umed and never submitted to. The civility of all
sses in the United States is so universal, that, during
intercourse with the inhabitants, I scarcely expe-
nced an indication of insolence, and never observed
t democratic sauciness which I was taught to expect
ongst the lower orders."

There are certain laws in the United States which
ve a peculiar influence on the manners of the country.
is not, for instance, allowed for a rich proprietor to
ve the whole of his wealth to any one of his children;
laws direct that it shall be divided equally, or nearly
among the whole. Hence large properties are
oken down, and the aristocracy of landholders, the
st important class in all other countries, have no ex-
nce in the states. As it is this class which in Europe
es the tone to a great many of the observances and
n feelings of society, the want of it in America has
owerful influence in forming a set of manners diffe-
t from ours; the farmers there are almost univer-
ly the proprietors of the land which they occupy,
d it is seldom very extensive. They have no rents
pay, and they cultivate only the best soils; hence
y have always large returns on their outlay; and
ough few of them acquire great fortunes, the majority
in easy circumstances. Some of the southern
nters, who are the richest *class* in the United States,
ve incomes as high as £18,000 or £20,000 per annum;
ny have from £3000 to £5000, but the incomes of the
jority do not probably exceed from £700 to £1500
annum. The next class to the planters, in point
wealth, are the great merchants in the commercial
ies, some of whom possess fortunes of £250,000;
se, however, are not numerous. As none of these
ns are, however, equal to the large fortunes which
inherited in Europe by the accumulations of several
nerations in one person, it is evident that there can-
exist in America those clubs of enormously wealthy
lividuals, who have such a powerful influence in all
affairs of the older countries. Extensive concerns
d great establishments, which in other countries are
pported by single individuals, are here carried on by
nt-stock companies: not only is this the case with
ks and canals, but with mills, steam-boats, woollen,
ton, and iron manufactories. The shares in the
cks of these companies are generally small, and thus
ord a ready means for mechanics, labourers, and

persons of all classes, investing their savings with advantage.

From the comfortable circumstances in which people of the middling classes generally find themselves, there are not the same restraints upon their moving from place to place, to improve their circumstances, as there are in Europe. Young persons have never the apprehension, for instance, of leaving their parents destitute, or dependent upon others, which often keep them at home with us. Married people, again, with a growing family, have generally a sufficient stock to enable them to move away with all their children, and take a long journey in whatever direction they may see a prospect of thriving. In England, where they have hardly a sufficiency from one day to another, this would be impossible; and hence the small number of working people in this country who are able to transport themselves to take advantage of the higher wages and better living of America. The journey by canal, river, and lake, to some of the back settlements there from the coast, is more expensive than that of an English family would be to Halifax, and the improvement of circumstances hardly so great; yet how few in this country, to whom this improvement would be the greatest, are able to take advantage of it! This power of shifting their place, and seeking to better themselves, has had a more peculiar effect upon the character of the Americans than any other circumstance. They have less of that superstitious attachment to one spot than is found in poorer countries, where the people cannot leave it: families think little of a journey of some hundreds, or even thousands of miles; and the numbers who are continually moving with their luggage, has made the opening of new canals and railroads to distant parts more profitable than it could have been in any other country.

RELIGION.

All forms of religion are equally favoured by the state in America, and the members of all have equal privileges. None of the clergy are paid by government, or out of public property, in any shape; they depend for their salaries entirely upon the congregations for which they officiate, and by which they are elected. The bishops, ministers, elders, or other officers, are chosen by the members of each persuasion, according to their several forms of church government, without the intervention of any other party. There are a great number of different denominations of Christians in America; the principal are the same as in this country, consisting of Catholics, Protestant Episcopalians, Presbyterians, Quakers, and the various classes of Independents. In some of the states there are certain denominations more prevalent than others. New England, for instance, was settled by the Puritans in Cromwell's time, and its religious condition bears the impress of that origin. Maryland was colonised by Roman Catholics, who are still numerous there: Pennsylvania by the Quakers or Friends; while Episcopacy prevailed in Virginia, the Carolinas, and Georgia. The first Presbyterians came from England, Scotland, and Ireland, and settled in Delaware and New Jersey. If the whole population of the states were divided into twelve parts, three of them would be Calvinists, chiefly of the Independent and Presbyterian sects; two Baptists; two Methodists; one Episcopalians and Lutherans. The rest include persons of many various forms of belief, and a considerable number who follow no religious profession.

There are about sixty colleges and seminaries for the education of young men devoted to the church, of all the different sects. In New York, it is found that there is one clergyman to every 1384 of the population; in Pennsylvania there is one to every 1123; in Kentucky, one to every 1377 of the white inhabitants. In Great Britain, the proportion is one to every 800 or 900—in Europe generally, one to every 1000. It must be recollected, however, that in America this whole number *are actually employed in* the ministry; there are none of them who are merely dignitaries, or who hold offices without labouring for the instruction of the people: this renders the proportion of actual religious teachers greater than at first sight it appears, when compared with the number of clergymen in European countries.

These remarks apply chiefly to the old-settled states of the east and north; and on this subject we beg to give the following extract from the work of a recent traveller of our own country, Mr Fergusson of Woodhill:—

"The religion of the states is marked by some peculiar features. It has been too frequently disgraced by wild and extravagant fanatics, and Unitarianism has in many places made dreadful strides. Still, the conclusion to which I have come is favourable to the growth of pure and vital Christianity in the populous and civilised portion of the states. I observed, in public and in private, a decent observance of the Sabbath. The official papers of the government uniformly recognise the superintending care of a beneficent God. No shops were to be seen open on the day of sacred rest, still less were the theatres or places of public amusement; public travelling was not in general use, and the transmission of the mail on that day had been debated in the preceding session of Congress, when the question was lost, chiefly on the ground that the constitution forbade any interference by government with matters of conscience. There can be no doubt, however, that Sabbath profanation is practised in some quarters to a great extent. As regards the fruits of religion, there can be little question, that, taking them as a people, the citizens of America are virtuous and exemplary. Conjugal infidelity is extremely rare, and in more than one of the states is visited by fine and imprisonment. In the large cities, at least of the middle and northern states, vice does not stalk abroad in that disgusting form which may be said to deprive respectable females in European towns of the free enjoyment of our public spectacles and walks."

We give one more extract on this subject; it is from Mr Stuart of Dunearn:—

"We went to attend divine service at Mr Stebbing's church. He had gone from home, and was unavoidably detained; and the person who had promised to officiate for him failed to appear, in consequence of the morning being stormy. The congregation assembled—a pause ensued: at length Dr Smith, one of the elders, rose, and said, that they ought not to separate without discharging those religious duties which had led them to assemble on the first day of the week. He then gave out a psalm from his own seat, and afterwards prayed. In the mean time, he had sent home one of his daughters for a volume of sermons, one of which he read. A second psalm was given out by him and sung, after which the service was concluded by a prayer from Mr Lister, a farmer in the neighbourhood, and one of the elders—the whole without any appearance of bustle or exertion." There are a great number of religious newspapers in America, which is a further proof of the serious habits of a large part of the population.

The remarks we have here made apply exclusively to the New England states, and to the older settled districts of the east; they may also perhaps be extended to the *towns* of the newly-formed western states, in which much attention is given to religion. In the slave countries, however, this condition is altogether reversed. North Carolina, with a population of 600,000, has hardly fifty clergymen; and South Carolina, with 420,000 inhabitants, has not more than forty. In Georgia there were only ten in 1818. In Virginia, the population is about one million; the number of clergymen not one hundred. The situation of Maryland is similar.

In the countries on the Ohio, Michigan, &c., which are in progress of settlement, there are no regular churches except in towns; the only opportunity the colonists have of attending sacred ordinances being at field-meetings, or *tent-preachings*, as they would be called in Scotland, which are held in the forests, and

ent of the state of education applies equally to every
rict. It relates, indeed, chiefly to the great towns,
to the thickly peopled places in their neighbour-
d. The remote townships, which in a country so
y occupied form a large proportion of the whole
, are frequently as much deficient in the means of
ruction as in regard to religious edification; and
have indeed little anxiety to improve themselves.
y of them pay no attention to the regulations for
ishing schools, and, were it left to themselves,
ld allow their people to remain as they are, without
r reading or writing. In America, however, as
ost other free countries, the well-informed portion
e community is the most active, and, like the little
m which leavens the whole lump, it is continually
ork to stir up a desire for information and light in
he dark places around it. The operations of bene-
nt societies have the same effect in the remote dis-
s of America which with us they have produced in
Highlands of Scotland and elsewhere; and they are
nately more successful, because, whenever a desire
information has been excited, the comfortable cir-
stances of the people enable them to go on educat-
themselves. In all the newly settled states, lands
e been allotted for the erection of academies, and
establishment of regular district or parochial schools,
rding as the population increases; six hundred and
y acres are generally set apart in each township for
purpose, besides one or two entire townships in
state for university funds.

LEARNING AND THE ARTS.

merica has produced several names of the highest
hority, both in learning and the arts. Classical
dies, which used to be looked on as the great test
earning, are not very extensively cultivated; but
eneral philology, or acquaintance with the prin-
es of language, this country possesses several very
nent scholars—among whom we may mention Mr
onceau, a native of France, but naturalised in
erica, and celebrated for his researches into the
ory and affinities of the different Indian tongues.
Wheaton, also, who is well known for his acquaint-
e with the languages and history of the north of
rope, deserves to be mentioned; and a Dictionary
the *English Language* has been published by an
erican scholar, Dr Webster, which was reprinted
England, and is highly esteemed. Many American
ters of the present day have attained very high
e, and their works stand side by side with the
t English authors. To mention those only which
well known in Europe—there is Dr Channing and
athan Edwards in divinity; Irving, celebrated both
a historian and a novelist; Bryant, a poet of high
er and elegance; Cooper, whose fictitious narra-
s have attained a fame hardly inferior to those of
tt, and which exhibit a set of manners completely
ginal to Europeans. It is questionable, indeed,
ther there is not as great a proportion of living
erican writers who have attained celebrity in Eng-
d, as there are of English authors of the present
whose works are read on the other side of the
antic. The American reviews, which often give
blicity to the opinions of men of talent in that
ntry, as ours do to those of philosophers and states-
n here, produce frequently as deep an impression
any European publications of a similar kind; and
selections which appear now and then in this
ntry from the American periodical literature, give
dence of as high talent in the writers, and of as
tivated taste in the readers for whom it is prepared,
any thing of the same description among our-
ves.

'There is in this country no class of men who can be
led authors by profession. Almost all the works
ich have issued from the American press have been
itten by men who have been engaged in some labo-
us profession or employment. These works have not
n written under the shelter of academic bowers, or

in the vicinity of large and well-furnished libraries, but under circumstances of inconvenience and embarrassment. It would therefore be unreasonable to expect that they should indicate that degree of erudition and literary culture which might be looked for under more favourable circumstances. Dr Franklin, the greatest American philosopher, followed during most of his life the profession of a printer; and Dr Bowditch, the most eminent American mathematician and astronomer, was, during his whole life, devoted to business relating to navigation and commerce, or finance. The most distinguished American theologians, as for example, Mather, Edwards, and Dwight, were devoted to laborious professional duties.

Since the beginning of the present century there has been a vast increase of persons who have written for the press, and also of the number of works published." The American Almanack, from which the above is quoted, gives a list of 776 names of American writers. The same authority estimates the number of copies of newspapers circulated in the United States at 100,000,000.

In science, the reputation of Europe is so compacted of what her philosophers of former times have done, and of what is now doing by those who continue their researches, that it would be absurd to institute a comparison in this respect. It may be remarked, however, in regard to America, that she possesses men who keep pace with all the discoveries and improvements of the sciences, and who are able to canvass and examine every thing which any new train of investigation may bring to light in other countries: if we add, farther, that one of the most splendid of these original trains of investigation was devised and traced to its result—the identity of the electric fluid with lightning—by the American philosopher Franklin, we shall have said as much for the scientific fame of America, as can be arrogated to itself by any European country. Of the American journals of science, that of Dr Silliman is well known in Europe, where it enjoys a high and well-merited celebrity. The recent growth of every thing in America has not given time as yet for the formation of those extensive museums and libraries which so much facilitate the researches of learned men in the old countries of Europe; and as the legislature has not power to vote money for these objects, it may be a considerable time before any thing is witnessed there like the splendid national collections of Paris, London, and Rome. There are, however, several museums: as, for instance, those at Salem, Boston, and Philadelphia, whose fame will gradually accelerate their own increase, and may at last attract national attention to the subject. There is no public astronomical observatory in the states, and the expense would be too great for any private means.

In mechanical science, which is the absorbing pursuit of the present day, the Americans have been no whit behind other nations in devising means for facilitating and abridging such processes of labour as are carried on in their own country. Steam navigation, though certainly first discovered in Scotland by Mr Taylor, was as certainly first brought to a useful and practical result in America by Mr Fulton. The machine which was contrived by an American for separating cotton from the seed—that for distilling salt water, or procuring sweet water at sea, by separating it from the salt—some contrivances for abridging the manufacture of iron-work—and many others adapted to the peculiar circumstances of their country—show the Americans to be equally ingenious, and equally acquainted with the resources of mechanical invention, as the English or any other nation.

The science of the Americans, as we have seen, has also been displayed in a very remarkable and useful manner, in the construction of several large canals and railways, some of which are hardly to be equalled in any other country. The same skill is exhibited in improving the navigation of their rivers, in constructing bridges, in architecture, and in ship-building.

FUTURE PROSPECTS OF THE UNITED STATES.

From the rapidity with which the population states has hitherto increased, and is diffusin over the wide and fertile continent of which possession, the most magnificent anticipatic formed by the Americans of the future great their nation. "Let us assume," say they, appears highly probable, that the people of the States will ultimately spread themselves ov whole North American continent west of the sippi, between the parallels 30° and 49°, as far Pacific Ocean. This will be found to add 1, square miles to the territory east of the Miss and, putting both together, the area of the States, thus enlarged, will be 2,700,000 square A surface of such extent, if peopled to the de Massachusetts, would contain two hundred m or if peopled to the density of Great Britain a land, four hundred and thirty millions. If the lation of the United States continue to multiply same proportion as hitherto, it is demonstrab the two hundred millions, necessary to peop vast territory, will be produced within a ce These are indeed magnificent anticipations, know no reason why they should not be realise we must remark, that, whatever they may add national greatness of the American name, they no means likely to be favourable in the same to the individual comfort of the members of its lation. It cannot be doubted but that the hig of wages and profits, and the rapidity with whic tal now accumulates in that country, are partly to the large tracts of fertile and easily accessib which are always at the disposal of its inhal Were the government weak, ignorant, or partia unoccupied territories might exist, as they do i other countries of the world, without being of tage to any one. In America, the qualities government render them easily available, as l they last; but nothing can renew the same adv after it has once been expended. As those s prospects, in which the Americans are fond of ind approach to realisation, the quantities of new la be daily growing less—the rapidity with which now accumulates will be diminishing in the sam portion—the wages of industry will gradually fa and as the nation becomes greater and more pov in the same degree will the resources of its ind population be lessened. But the truth is, these f concerning the rapid increase of population, a filling of the whole American continent with a of unparalleled power, "greater than the sands sea in multitude," are mere playthings of the nation. Too little is known of the real numerica gress of population to enable us to say any thing subject; and certainly it is not the circumstanc their immense and fertile country *will one day b occupied*, which ought to be a subject of satisfact pride to the Americans, however powerful the might then be, but rather that their gigantic popu has rich fields and abundant pasture in which to on its increase for many ages. During this time, i set an example of equal government and peacef dustry to the rest of the world, which, unhappily been hitherto wanting; and by the reaction of just ciples on the influential part of the old continen new nations of the west may be the means of rede it from many oppressions. When these are rea it will be seen, that, in our world too, there i wanting abundance of unoccupied and rich land: kingdoms and provinces of Europe, Asia, and A are at present shut up from industry by one ki barbarism or other, and the example of Americ yet enable mankind to enjoy the advantages of fertility.

fountains of great size might be swallowed up
almost fathomless ravines, at the bottom of
ly the astonished traveller can judge of the
gnificence of the mountains.

ne respect is South America more distinguished
he number and magnitude of her rivers, some
might with propriety be described as *running*
Of these the Amazon, or Maranon, claims
ank. For a space of 22°, in a direct meridional

distance, not a single stream descends the eastern side of the Andes, but what contributes to swell the ocean-flood of this river, which, for length of course and volume of water, has no parallel in the world. The main trunk is composed of several very large streams, its chief effluents being derived from the south. First is the Huallaga, whose source may be traced to the neighbourhood of Lima, not far from those of the Maranon itself. The next is the Ucayale, a river not inferior to the Maranon at its junction, and sometimes held to be the true Maranon. The Purus, or Cuchivara, is also a river of the first class; but the most celebrated of these tributaries is the Madera, formed from the Beni, the Marmore, and the Itenes. The Rio Negro, which comes in from the north, is likewise a very large stream. Having said this, we must refer the reader to the map for a description of its onward course to the ocean. The total navigable course of the Maranon is calculated at upwards of 3000 miles in a direct line; but the length of its course is estimated at 4095 miles. Ships of 500 tons burden might ascend it for 2500 miles, while many of its tributaries are equally navigable almost to their source. More than one-half, indeed, of this vast continent might enjoy a maritime shore from these numberless streams, any of which would spread commerce and civilisation through a widely extended empire. The territory watered by the chief stream and its branches is at least equal in extent to continental Europe, and may be stated at 2,177,000 English miles. There are no sand-banks, nor shelving rocks, nor ice at any time of the year, to impede navigation; and so strong an easterly wind blows constantly from the Atlantic, as to carry up vessels against the tide. Yet, notwithstanding all these advantages, the mighty Maranon rolls on its course through regions unknown to industry or civilisation. Throughout its whole course it is studded with large and fertile islands, from five, ten, twenty, to a hundred leagues in circumference. The waters of this mighty stream, and those of its tributaries, are stored with an infinite variety of fish of the most delicious kinds.

The La Plata, Plate, or Silver River, is next in magnitude to the Amazon. It is composed of three principal streams, the Parana, the Paraguay, and the Uruguay, and receives all the waters that flow from the eastern declivity of the Chilian Andes, and from the southern, south-western, and western faces of the Brazilian mountains. The three principal streams, with their tributaries, offer facilities for inland navigation little inferior to the Amazon itself. The estuary of the La Plata is broader than the British Channel. The length of its course is estimated at 2430 miles, and the area of its basin at 1,240,000 miles.

The Orinoco is the third largest river in South America, but much inferior to the two above mentioned. Through a direct course of about 1200 British miles, it receives all the streams that water the Caraccas and New Granada, with the exception of the coast rivers. It was only about fifty years ago that there was discovered a communication between this river and the Amazon, by means of the Rio Negro. Humboldt, who has since explored these rivers, has accurately laid down the previous courses and junction of the Rio Negro and the Orinoco. In one part of their course they flow along a level plateau, which has little or no declivity; their branching waters meet and mingle in a sort of basin; and when thus united, they form what is called the natural canal of Cassiquiare. There are several cataracts and rapids on the Orinoco, described by Humboldt as splendid in the extreme. There are some other very large streams in South America, particularly in Brazil; these will be noticed when we treat of the individual countries in which they occur. There are likewise some large lakes, which will be described in the same manner.

CLIMATE AND VEGETATION.

A country embracing so many degrees of latitude and *elevation, possesses of* course equally diversified degrees of climate. "The three zones of temperat originate in America," says Malte Brun, " the enormous difference of level between th regions, cannot by any means be compared zones which result from a difference of latit agreeable, the salutary vicissitudes of the se wanting in those regions that are here disting the denominations of *frigid, temperate, hot,* In the frigid zone it is not the intensity but tinuance of the cold—the absence of all viv the constant humidity of a foggy atmosph arrests the growth of the great vegetable pr and, in man, perpetuates those diseases that checked perspiration. The hot zone of th does not experience excessive heat; but it tinuance of the heat, together with exhalatio marshy soil, and the miasmata of an immens vegetable putrifaction, added to the effects treme humidity, that produces fevers of a mo destructive nature, and spreads through animal and vegetable world the agitation of rant but deranged vital principle. The tempe by possessing only a moderate and constant like that of a hot-house, excludes from its li the animals and vegetables that delight in the of heat and cold, and produces its own peculi which can neither grow above its limits, no below them. Its temperature, which does the constitution of its constant inhabitants, spring on the diseases of hot regions, and lik on those of the frozen regions. Accordingly journey from the summit of the Andes to th the sea, or *vice versa*, proves an importan agent, which is sufficient to produce the most ing changes in the human body. But living in either one or the other of these zones, m vate both the mind and the body by its m tranquillity. The summer, the spring, and t are here seated on three distinct thrones, w never quit, and are constantly surrounded by butes of their power. Vegetation presents number of gradations, of which it becomes to point out the principal.

In the region of the palms, next the sea, t cultivate the banana, jatropha, maize, and coc peans have introduced the sugar-cane and ind After passing the level of 3100 feet, all the become rare, and only prosper in particular It is thus that the sugar-cane grows even at t of 7500 feet. Coffee and cotton extend acro these regions. The cultivation of wheat co at 3000 feet; but its growth is not comple blished lower than 1500 feet above this line is the most vigorous, from a height of 450 feet. One year with another, it produces grains for 1. Above 5400 feet, the fruit of th does not easily ripen; but the plant is still although in a feeble condition, 2400 feet high region comprehended between 4920 and 51 also the one which principally abounds with or *Erythoxylum Peruvianum*, a few leaves mixed with quicklime, support the Peruvian his longest journeys through the Cordillera. the elevation of 6000 and 9000 feet, that the *dium quinoa* and the various grains of Europe cipally cultivated: their cultivation is greatly by the extensive plateaus that exist in the of the Andes, the soil of which being of smoot and requiring little labour, resembles the ancient lakes. At the height of 9600 or 10 frost and hail often destroy the crops of whea corn is scarcely any longer cultivated above tion of 7200 feet; 1000 feet higher and the produced; but it ceases at 12,600 feet. 10,200 feet barley no longer grows, and r sown, although even this grain suffers from heat. EARTHQUAKES AND VOLCANOES.

he whole of the active volcanoes known to exist
world, by far the greater number are scattered
hat range of mountains which has been described
nding, under the name of the Andes, from the
o the north extremity of South America, and
passing along the Isthmus of Panama into North
a, every where keeping near the shore of the
Ocean. South America is therefore eminently
nic region. From the 46th degree of latitude,
ard to the 27th, there is an uninterrupted line
e volcanoes; farther to the north, in Peru and
they are less numerous, but very lofty and con-
s. The volcanoes of Chili rise through granitic
ins; that of Villarica, which is so high as to be
sished at the distance of 150 miles, burns with-
ermission. In Quito there are some above 16,000
height, as Antisana, Cotopaxi, and Tunguragua,
which frequently emit flames. As a necessary
uence of so much volcanic action, the region of
des is remarkable for frequent earthquakes. In
carcely a week passes without some slight tremor
surface being felt. In Chili, it is seldom that a
unmarked by some considerable shock. About
century, or oftener, a tremendous earthquake
the greater part of the Andean region, destroy-
es and towns, and producing extensive changes
earth's surface. One of the most destructive in
a times was that which occurred at Caraccas in
when about 20,000 people in the city and sur-
ng district (16,000 of whom belonged to the city
were destroyed, being swallowed up by the rend-
he earth, or buried beneath the ruins occasioned
shock. One remarkable result of these great
sions is an elevation of the land. In consequence
great earthquake in Chili in 1821, the land was
several feet along a space of a thousand miles,
receding from it accordingly, and leaving dry
an extensive tract formerly covered by the ocean. Similar raised beaches are to be traced at various elevations along the slope between the sea and the Andes, showing that phenomena of the same kind must have taken place at different distances of time. Indeed, it is now the belief of geologists that the whole of the continent of South America has been raised out of the sea at a comparatively recent period; and it is ascertained that a sinking of it to the extent of only five hundred feet would again submerge the greater part. Humboldt is of opinion that the Andean volcanoes are but the spiracles of an immense *volcanic vault*, extending under the surface of this part of the globe, and part of which is covered by the bed of the Pacific. The connection of the volcano of Pasto in New Grenada with the volcanoes of Quito, was strikingly displayed in 1797. A column of black smoke had continued for several months to issue from the former, but it suddenly disappeared on the 4th February of the same year, at the precise moment when, at sixty-five leagues from the city of Pasto, the city of Riobamba, near Tunguragua, was swallowed up by an earthquake. This eruption was of a very extraordinary nature. An enormous area of ground rolled backwards and forwards, like the sea, for four minutes, during which time every town on its undulating surface was levelled with the ground, and the cities of Riobamba and Quero were buried under the ruins of the impending mountains. Tunguragua was rent asunder and vomited a sea of mud, covering the valleys to the depth of 600 feet.

NATIVES.

The question respecting the origin of the native population of both continents of America, seems to have been settled by the discovery of Behring's Straits, and there is now scarcely a doubt entertained of their descent being Asiatic. There are, throughout most parts of the interior of South America, innumerable hordes of Indians still living in a savage and primitive state. Of the general features of these people it would be in vain to attempt an enumeration here, as they are divided into thousands of small tribes, or *nations*, as they call themselves, all distinguished by their own peculiar characteristics. Many of them, such as the Chilians and Peruvians—and of the former, the Araucanians more especially—were certainly marked, from the earliest period of their discovery by Europeans, by many of the finest and noblest traits of human nature while in an unenlightened state—hospitable, faithful, social, peaceful, and affectionate; while those in other parts of the immense continent were conspicuous, as many of them indeed still are, for all the cruel, deceitful, bloody, and barbarous features displayed by the most savage nations.

SUBJUGATION OF THE COUNTRY BY EUROPEANS.

After the discovery of Brazil by the Portuguese in 1499, the country was taken possession of in the name of the sovereign of Portugal. In 1531, it was divided into captaincies, and granted to such persons as were willing to undertake their settlement. But these lords possessors abused their powers, and a governor-general was appointed, with full authority, civil and criminal. The first individual selected for this high office entered upon the duties of it in the year 1549. The Pacific Ocean was discovered in 1512 by Nunez de Balboa, governor of Darien, which a few years before had been colonised by the Spaniards. In 1524, the famous, or infamous, Francisco Pizarro landed in Peru, which he found in a partially civilised state, and governed by a race of princes named incas. In a few years he completely subjugated this simple, and, in many respects, amiable people. The treachery, cruelty, and perfidy, by which he effected his object, have rendered his name odious to mankind; but into details we cannot enter. An army was dispatched from Peru for the conquest of Chili, but this proved a very difficult undertaking, on account of the indomitable courage of the natives. Of all the aboriginal nations of America, the Pro-

ever, showed something of the spirit of the Chilenos, and were only subdued with difficulty. The territory of New Granada was formed into a government in 1547, and Venezuela in 1550. Quito depended on the government of Peru till 1564, when it was constituted a presidency. These three territories underwent repeated changes, but finally became known under the names of the captain-generalship of Caracas (Venezuela), the viceroyalty of New Granada, and the presidency of Quito. Guiana was settled in 1550 by some French Protestants, who had fled thither as to an asylum from the persecution of the League. The Dutch settled Berbice in 1626; Essequibo in 1698; and Demerara somewhat later. The history of the ill-fated colony of Darien, established by the Scotch at the close of the seventeenth century, is well known. The country situated on the shores of the Rio de la Plata remains to be noticed. A considerable part of the river having been explored by Sebastian Cabot in 1526, the region was taken possession of for the Spanish crown. Buenos Ayres (*good airs*) was founded in 1535, but soon after destroyed by the natives. It was rebuilt, but a second time reduced to ruins by the savages; and not until 1580 did the Spaniards succeed in their object of erecting a city on this spot. In the meanwhile Paraguay had been colonised, and the country conquered as far as Potosi. The permanent settlement of the Spaniards here was greatly facilitated by the Jesuits, who founded those celebrated communities called *reductions*, or missions, in which they made strenuous efforts to civilise the natives, and bring them within the pale of Christianity.

CONDITION OF SOUTH AMERICA UNDER THE SPANIARDS.

The power of Spain and Portugal having been firmly established over the greater part of the South American continent, such methods of government were adopted as seemed best calculated to secure the allegiance of these territories to the mother countries. That the measures to which the Europeans had recourse for this purpose were tyrannical and most oppressive to the natives, may be taken for granted. We shall, in the first place, treat of the Spanish dominions, leaving Brazil to be noticed afterwards. The whole of the Spanish possessions in the new world were originally divided into two immense governments, one subject to the viceroy of Mexico, and the other to the viceroy of

before the great revolt of the American pro- f Spain, partial attempts to shake off her e yoke were made in several of the provinces; have seen that it was never very securely upon the warlike natives of Chili. The most ble of these efforts to achieve independence made by Tupac Amaru, in the year 1780. ed to be a descendant of the last inca of Peru, beheaded in 1562; and to give eclat to the e assumed not only the name of his ancestor means *the highly endowed*), but the style and the incas. The immediate cause of the revolt shameful avarice of the corregidors of some who imposed upon the Indians more reparti- than the law gave the authorities power to them. At first it wore a very serious aspect, ultimately suppressed, after one-third of the opulation of Peru had perished by violence. mpt at revolution was made in Venezuela in d another in 1806, both without success. But ere taking place on the continent of Europe, singularly enough, were completely to change inies of South America.

THE WAR OF INDEPENDENCE.

a remarkable fact, that the first revolutionary mt originated not in a spirit of resistance to the by which America was oppressed, but in a enthusiastic loyalty to the imbecile Ferdinand, ereign ruler of Spain and the Indies. When narch was deposed and imprisoned by Napoleon, conqueror's brother Joseph was placed on the orders were dispatched to the colonies to their submission to the new dynasty. But they to transfer their allegiance from Ferdinand loved" to a usurper, although he was the brother oleon, who had then just reached the zenith of er. In this the Americans showed a great and ndable spirit of independence—it was a good f what should soon take place. On the 15th of 08, the people of Caracas took the lead in ning Ferdinand VII., the captain-general and ia being compelled to give way to popular feel- d a solemn oath of allegiance to the legitimate h was taken by acclamation. By an ancient it was provided, that, in cases of emergency, ivocation of cortes or general juntas, in the ive kingdoms of Spanish America, might take Here, then, was an emergency as momentous that could possibly occur. They were about transferred from their legitimate monarch to er of France, as if they had no voice in the whatever, and this they would not tolerate. The exercise of the right legally and constitutionally vested in these juntas seemed the best means of saving the colonies from the yoke of France. Yet such was the singular state of affairs at the time, that this demonstration of attachment to the lawful sovereign proved the signal for the declaration of hostilities by Spain, and the commencement of a war of extermination. But how could it be otherwise? Napoleon was now omnipotent in the mother country, and the loss of any of her colonies, which their standing out for Ferdinand must have virtually been, was not likely to be tolerated. So that instructions to the powers in the colonies to suppress any demonstration of the kind, followed as a necessary consequence of the position of the Spanish crown, and the affairs in the peninsula at the time. But a flame was kindled which was not to be quenched even at the fiat of a Napoleon. We are far, however, from thinking that ardent attachment to legitimacy was the sole or even the leading motive which determined the simultaneous movement which took place throughout the whole of Spanish America. It was the ostensible ground for the formation of juntas, but entire independence was clearly the ultimate aim of thousands, who were content at first to mask their operations with this disguise. In Caracas, the supreme junta assembled on the 19th of April 1809, and one of its first acts was to banish the captain-general and the members of the audiencia. Juntas of government were convened at La Paz, in Upper Peru, on the 15th of July in the same year; at Quito on the 19th of August following; at Santa Fe de Rogota on the 25th of May 1810; at Buenos Ayres on the same day; and at Santiago of Chili on the 18th September.

Buenos Ayres has been called the cradle of South American independence; yet at the period of the first British invasion of that city, Spain had nowhere more loyal subjects. But many of the inhabitants had grown rich by trade, and enlightened views had become disseminated amongst them, so that, although they displayed equal zeal with the other colonies in the cause of Ferdinand, they did not long conceal their design of ultimately erecting the standard of independence. Attempts were made to foist upon them a lopped-off scion of the royal stock of Portugal, but this scheme proved abortive. After some political squabbling, Cisneros, the viceroy, was deposed, and banished from the country along with the oidores. The junta, consisting of nine individuals, amongst whom were some very able men, now made no secret of their intentions. The people acquiesced, and thus, without bloodshed, a complete revolution was effected in Buenos Ayres. The city soon felt itself powerful enough to proselytise in the distant provinces of the viceroyalty, where some royalist generals had collected bodies of troops, declared against the revolution, and taken measures for putting the question to the arbitration of the sword. The army of the republic was entrusted to Balcarce, and its first campaign proved completely successful. Cordova, a city of the interior, attempted to change the course of events, but all opposition in this quarter was speedily suppressed. On the 27th of October and 7th of November 1810, the royalists were defeated at two different places on the distant frontiers of the viceroyalty. These successes gave Balcarce possession of the country as far as the Bridge of the Incas, near the great lake of Titicaca; and on the 25th of May 1811, the first anniversary of independence was celebrated on its shores, amid the ruins of the ancient incarial palace, 2000 miles distant from Buenos Ayres. Meanwhile Castelli, a man of great talents but most reckless temper, had joined Balcarce, having been sent to act in concert with him, and to assume the governorship of Upper Peru. But whilst the cruelties of this chief struck terror and dismay to the hearts of the Spaniards, his dissoluteness and want of attention to the affairs of the provinces, alienated the affections of the inhabitants of Upper Peru from their deliverers, and the common cause of both. This gave opportunity for Abascal, viceroy of Peru, striking a powerful blow in

patriots, who assembled in considerable numbers, and sought an asylum amongst the neighbouring mountains. The history of Buenos Ayres becomes now closely interwoven with that of Upper Peru. Indeed, the transactions which took place throughout the whole of the governments, are intimately blended with one another. A principle of mutual assistance was acted upon, and armies successful in one place marched many hundred miles to the assistance of their fellow-patriots, who were hardly pressed by the Spaniards in another. Thus the troops of different provinces, or republics, as they soon were designated, became mixed together, and Buenos Ayreans, Chilinos, Bolivians, Peruvians, and Colombians, fought side by side on the same field. This friendly co-operation amongst the republicans greatly contributed to their success; the struggle might otherwise have been protracted in many places, till a period long subsequent to that when the Spaniards were finally expelled from South America.

We have already had occasion to notice the valour and patriotism of the natives of Chili, so that the reader is probably prepared for a speedy overthrow of the Spanish power in that quarter; but events often take a very different course from what they at first promise, and from what is anticipated. The first revolutionary movements, indeed, were here accomplished without difficulty or violence, being greatly facilitated by a commissioner sent from Buenos Ayres. The Spanish governor was deposed; a junta was formed on the 18th September 1810, still, however, acknowledging the supremacy of Spain; and in spite of attempts to upset the new government, a congress met in June 1811, when many wise measures were adopted. Reforms in civil and ecclesiastical establishments were projected; freedom of commerce and of the press was declared; and this was the first legislature in South America which adopted efficient measures for the extinction of slavery. But the smiling aspect which affairs began to assume was soon overcast by the ambition of three brothers named Carera, who succeeded in forming a new government, and dividing the interests of the country just at the very moment when union was almost indispensable to the existence of the new system of things. The Spaniards in Peru took advantage of the crisis, landed an army in Chili, and seized the city of Conception and some other places. This occurred early in 1813. The Chilinos were not long in making head against the foe, and a bloody battle was fought, in which the patriots were victorious, the Spaniards retreating to a town which they strongly fortified. But various engagements took place, in which the royalists were generally successful, and by the end of 1814, the principal Chilinos leaders were forced to seek refuge beyond the Andes, which divide Chili from the plains of La Plata. Once more, then, the Spanish power became dominant in Chili, but its ascendancy was of short duration, for the celebrated general, San Martin, who makes such a figure in the subsequent history of South America, was at this period busily employed in organising an army for the liberation of his country, and with which he in no long time achieved it.

In New Granada and Venezuela the struggle was more bloody, variable, and protracted, than in any other part of South America. This portion of the dominions of Spain being comparatively easy of access, *and, from its central position*, to a certain extent a key *to the whole, she made* proportionate attempts to retain

united provinces of La Plata, or the Argentine blic, comprises the whole of that vast space ex- g from the cordillera of Chili and Peru to Brazil, he exception of Paraguay and the Banda Oriental, are independent states. It extends from the 22d 41st degree of south latitude, and from 55 degrees nutes to 71 degrees of west longitude, comprising ea of 720,000 square miles English, and divided irteen provinces, which, to a certain extent, govern elves independently of each other, but for all gene- national purposes, are confederated by conven- agreements. For want of a more defined national tive, the provincial government of Buenos Ayres porarily charged with carrying on the business union with foreign powers, and with the manage- of all matters appertaining to the republic in com- The executive power of that government, as con- d in 1821, is vested in the governor or captain- al, as he is styled, aided by a council of ministers nted by himself, responsible to the junta, or legis- assembly of the provinces by which he is elected. unta itself consists of forty-four deputies, one-half om are annually renewed by popular election. It t first attempted to establish a system of fede- , by which Buenos Ayres should exercise imme- control over the other provinces; but from various s the plan proved quite abortive. The national ization of this state is now limited to the slender

bonds of voluntary confederation, not only with each other, but with the old metropolis, Buenos Ayres. The whole territory is an almost uniformly level plain of great fertility, watered by the large rivers La Plata, Parana, Paraguay, and Uruguay, and several others of smaller dimensions; the Talado, Pileomayo, Vermijo, Nuevo, and that which empties itself into the lake Solatos, being the most important. There are likewise a number of lakes, the waters of which are brackish. There are almost no natural trees in the province, but there are numerous plantations, or rather orchards, of peach trees, which the natives cultivate for firewood —the fruit being applied to feeding the swine and poultry. Immense forests of thistles spring up at certain seasons of the year, of ten and twelve feet in height. Deer are plentiful in the wilder parts, but little prized where there is so much fine beef. The climate is extremely salubrious, and, singularly enough, is almost entirely governed by the winds, which, generally speaking, are northerly.

One of the distinguishing characteristics of La Plata, are the vast plains called *pampas*, one portion of which extends from the banks of the Paraguay westward to the frontiers of Los Charcas, and northward to the mountains of Chiquitos—another immense plain, 300 miles in length from east to west, and 1500 miles from north to south, as far as Patagonia. These plains present one uniform expanse of waving grass, uninterrupted by either wood or eminence, although in some places parched and barren, and perfectly uninhabited, unless by innumerable herds of wild oxen, horses, ostriches, and other animals. Over these pampas lies the only route by land from Buenos Ayres to Chili, which journey was formerly performed by large companies, as the plains were infested by hordes of roving Indians, who went there to hunt, catch wild horses, and plunder. From the absence of all permanent landmarks, the travellers over these immense plains shaped their course by the compass, and their caravans were in reality moveable houses, solid and defensible. Of late years, regular post-houses have been established along the whole line of road betwixt Santiago (the capital of Chili) and Buenos Ayres—a distance of nearly 1400 miles—and a regular communication is kept up betwixt the two republics by means of couriers, who perform their journeys with uncommon speed.

The city of Buenos Ayres is situated on the southern margin of the river Plata, where the latter is formed by the confluence of the Parana, Uruguay, and Negro rivers. It is thus, as it were, the key to all the internal navigation. The length of the Plata, from its formation to the ocean, is upwards of 700 miles. The city occupies a large extent of ground, being about two miles long, and a mile and a half broad, all the streets crossing at right angles. There are a university, several educational establishments, and a number of churches. The prosperity of Buenos Ayres and the other provinces is greatly impeded by the defective navigation of the river Plata, which is filled with shoals and sandbanks, and therefore dangerous to large vessels, otherwise the city of Buenos Ayres would become one of the largest emporiums of commerce in the world. The rivers Parana and Uruguay are each navigable for vessels of from 200 to 300 tons, 1500 miles into the interior; the former running through Paraguay into the centre of Bolivia. In 1806, Buenos Ayres was taken by a small English expedition, under Admiral Popham and General Beresford; but the inhabitants, recovering from their surprise, soon afterwards drove their assailants from the town. In the following year, General Whitelocke arrived with reinforcements; the troops were quietly permitted to enter the town, when they were repulsed with great slaughter, and ultimately compelled to evacuate the La Plata. There were no fortifications at the time the city was attacked by the British troops, and it was indebted for its strength solely to the peculiar structure of its buildings.

The estimated population of the provinces of the Rio de la Plata in 1836–7 was from 600,000 to 675,000, exclusive of independent Indians within the ter laid claim to by the republic. Of this number habitants, from 180,000 to 200,000 were reckon belonging to Buenos Ayres. Into details of tra cannot enter; indeed, it is impossible to obtain c information regarding the interior provinces, their merce being mostly of a domestic or internal n Buenos Ayres is of course the great centre of fo trade. In 1837, the imports from Great B amounted to £696,104; the total imports into t public being valued at 7,000,000 dollars. The e during the same year amounted to 5,637,138 d consisting chiefly of ox hides, gold and silver, s wool, jerk beef, horse hair, tallow, sheep-skins other products of the country. Of late years, th ports into Buenos Ayres have decreased, whilst of Monte Video have increased.

PARAGUAY.

The republic of Paraguay, formerly one of the provinces of the vice-royalty of Buenos Ayres, i ated between the rivers Parana (on the east and and Paraguay (on the west). It is divided by a tract from Brazil on the north. It comprises a of about 50,000 square miles, with a population of 250,000, seven-tenths of which are Creoles.

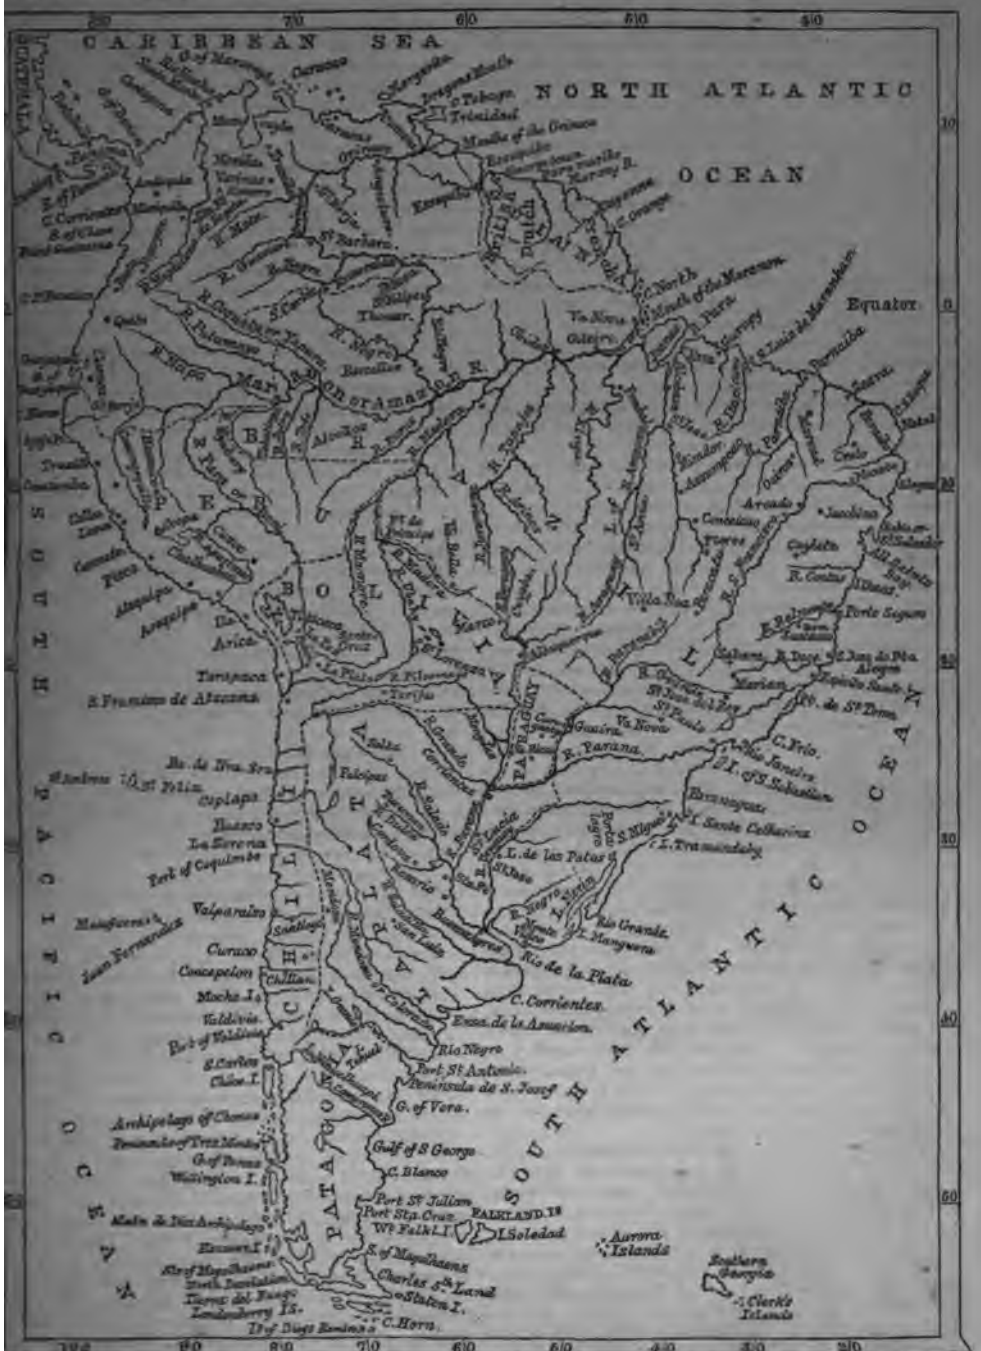
The climate of Paraguay is mild and healthy, alt moist, being low and level. All sorts of tropical corn, vines, sugar-cane, rice, maize, tobacco, indig a number of valuable medicinal plants, abound i fusion. There is a particular plant peculiar to guay, called *yerba*, and, when decocted, *matte*, greatly resembles the tea of China, and is by preferred to the latter. It is universally used in America. Of late years it has been cultivated in with great success. Immense herds of cattle roam the vast plains, whose hides and tallow form an of commerce.

From shortly after the declaration of indepen in 1811, until 1838, this beautiful and prolific was governed in a despotic manner by Doctor Fr a man of considerable talent, but it is believed crazed in mind, who had the address, like Crom dissolve the temporary government established revolutionary party, and to appoint himself sol perpetual dictator of the state. All things wer managed by him; he planned roads, bridges, and public works, organised the army, and interfered most minute arrangements. His rule was sup by excessive cruelty, and he lived in constant f assassination. This extraordinary despot died, eighty-second year, in 1838; but what has be political condition of the state since we have not Some writers are disposed to think that upon the Francia's dictatorship was beneficial for the co as he carried on various objects of utility, and pr respect and tranquillity for his people.

URUGUAY, OR BANDA ORIENTAL.

This comparatively small state, which occasi long and bloody contention between the unite vinces and the Brazilian government, is situat tween the river Uruguay and the Atlantic from to north, and between the rivers Plata and P from east to west. From its position, betwee Spanish and Portuguese settlements, it soon beca object of contention; but it would be a waste o to follow the course of the struggle. Suffice it t that after much blood had been shed on both sid a war of more than half a century's duration, which the disputed territory, by being the co battle-field, was devastated by both, the conte parties at last drew stakes, and it was erected i independent state in 1829. It is equally distingu for fertility of soil, salubrity of climate, natural b and geographical position. It abounds in exc pastures, which are fertilised by an unusually number of streams, in which respect it is greatly rior to the rival provinces on the opposite banks

o de la Plata. The city of Monte Video, the capital the republic, is situated on the northern bank of the at river just named, near its mouth, 120 miles north- t from Buenos Ayres, in latitude 34° 50′ south, and gitude 56° 20′ west. The importance of this city greatly increased since the erection of the coun- into an independent republic. A lowering of the ties on import trade, whilst those of Buenos Ayres ained high, brought foreign goods to it, so that it has some measure supplanted its rival, and become an trepôt for the supply of the neighbouring provinces. This is the cause of the diminution in the amount of imports into Buenos Ayres, to which allusion has already been made. In 1836, the importations of foreign goods into Monte Video amounted to 3,500,000 dollars, whilst the exports were nearly equal in value, and now constitute an important proportion of the returns in the general account of the trade with the river Plata. The population of the Banda Oriental is estimated by Sir Woodbine Parish (1839) to be from 100,000 to 120,000 souls, and is rapidly increasing.



CHILI.

Chili is bounded on the north by La Plata, on the east and south by Patagonia, from which it is separated by the Andes, and on the west by the Pacific Ocean, along the shores of which it stretches from 21° to 43° of south latitude. It is 1300 miles long, and from 30 to 120 broad. The ground ascends gradually from the ocean to the Andes, but is intersected by their projecting branches, some of which run almost down to the sea-shore. There is no deficiency of rivers in Chili, but in general they are small, and running from the Cordillera to the Pacific, they have necessarily short courses. These streams are indispensable to the existence of agriculture, in a country where it rains very seldom, and to a very limited extent. The fertility of the soil of Chili has in many respects been much overrated. It presents great diversities. In some parts where irrigation is deficient, it is barren and unproductive; in others quite the reverse; and amid splendid woodlands, the finest crops of wheat, barley, rye, and other species of grain, are raised, with scarcely any trouble to the cultivator beyond scattering the seed. Cotton, sugar-cane, vines, &c., are also extensively cultivated. The country is perfectly free of all noxious reptiles, the climate salubrious, and the weather serene. The want of navigable rivers is unfavourable to commerce; and although there are many rich mines of gold, silver, and copper, in the northern provinces, the sterility of the country around them prevents many of them from being wrought.

In 1827, the directorship of Chili was changed into a presidency, in imitation of the United States. The established religion is the Roman Catholic, the priesthood not being numerous, as was the case prior to the revolution. The constitution of Chili is that of a federal republic, consisting of three states, namely, Coquimbo, Santiago, and Conception, and one district, Chiloe, each having a provincial assembly, and all four a common congress, or executive power, which holds its sittings at Santiago.

Chili is divided into eight provinces, which contain a population of about 600,000. The principal towns are Santiago, with 65,675 inhabitants; Valparaiso, with 26,000; Conception, with 10,500; and there are, besides, Penco, Coquimbo, Copiapo, and others of inferior note. In 1836, the outlay of the state was reckoned at 1,840,204 dollars, the receipts being above 300,000 dollars more, which served to pay the interest of the English loan, or, at all events, a part of it; for their affairs are in great confusion, and their debts are so mixed up with those of Peru, that it is difficult to determine how they stand. By allowing the interest of their loan to remain for years unpaid, the debt has accumulated in such a manner as to have destroyed national credit. The perpetual broils with Peru have materially contributed to retard the advancement of this country, which has certainly very considerable resources, and an enterprising and intelligent population. To enter into particulars regarding this long-standing quarrel, is not compatible with our limits. It originated in a loan which Chili gave to Peru, to assist her in the period of her distress, and which the latter has not been grateful or honest enough to refund. Peace and war have more than once been proclaimed between the two states within these few years, and so late as 1839 the army of Peru was, through treachery, it is said, nearly extirpated by the troops of Chili.—See PERU.

During the year 1834, there was exported from Chili, gold, silver, and copper, to the amount of 3,158,143 dollars. The other chief articles of export are hides, timber, wheat, flour, fruits, Cortex Peruvianus, indigo, tin, and seal-skins. The imports into Chili from Great Britain, chiefly of manufactured goods, amounted in 1835 to £606,176. The native manufactures of Chili are insignificant. A great number of islands stretch along the coast, and belong to this republic, but they are too *small and unimportant* to require special notice in this *place*. *Valparaiso* is the great port of Chili into which all foreign goods enter. In 1835, about 400 ves delivered their cargoes.

PERU.

Ever since the declaration of independence, P been a scene of political squabbling and chan the details of which we need not enter. In 18 country was divided into North Peru and Sout the chief power being vested in a supreme pr and a close intimacy was then entered into w neighbouring republic of Bolivia. The cons established by a congress of the three confe states of North and South Peru, and Bolivia, is n upon that of the United States of North Americ of the three republics was to have its own distri gress, and, collectively, they may be said to have a federal republic, united to one another for support and protection. The head of the confe was chosen by the general congress, out of six dates proposed by the three republics. The firs appointed to the protectorship of the Peruvio-B confederation was General Santa Cruz, who t tually became the head of three independent He was elected for ten years. With regard to t stitution of each republic, little appears to ha agreed to besides the general principle that the ment of the countries should be entrusted to and house of representatives.

We have already alluded to the declarations which have passed between Peru and Chili. ties do not appear to have yet terminated, a infant states, instead of bending their energies developement of the resources of the country, a ing each other to pieces by the bloody and eve game of war. A squadron from Chili took th Lima, in August 1838, after an action in whi men were killed. Santa Cruz immediately a upon the city, but in the mean time the Chili evacuated it, and penetrated farther into the They were followed by the Bolivian chief with siderable army, but, in January 1839, he allow self to be surprised, when nearly his whole troo either killed or taken prisoners. Santa Cruz so published a proclamation, by which he abdica protectoral authority over Peru; and, by another he resigned the presidency of Bolivia. It were speculate how matters will terminate; but in a hood Bolivia will remain a separate state, and and South Peru will again amalgamate and fo republic.

The boundaries of North and South Peru ar so imperfectly defined, that in our description region we shall consider them as forming one Indeed, it is very probable, as we have said, th will soon again be united as formerly. Peru from 3 degrees 34 minutes to about 22 degrees latitude, and from 62 degrees to 82 degrees longitude. Its length is computed at 1500 mi its coast line on the Pacific Ocean cannot be le 2100, reckoning the bendings of the shore. Ac to Humboldt's estimate, Peru comprises an 45,500 square leagues. The surface of this va tory is of the boldest and most varied descripti is naturally divided into three regions, Western situated to the west of the Andes; Eastern Pe ated to the east of that mountain chain; and the Andes, which comprises the mountainous Western Peru is a belt or zone of sand near miles in length, and having an average bre thirty or forty miles. No rain falls through whole of this desolate Sahara of the west, and tion only springs up on the banks of the river run from the Andes to the Pacific. The h parts of Western Peru, therefore, are merely of oases "islanded amid the waste of sand," li of Africa. Yet here are situated the city of L several other large towns, the only sea-ports o public. Peru of the Andes, as might be inferr its varied elevation above the level of the s

ents a great diversity of soil, climate, and vegetation. uffice it to say, that in different parts it exhibits every pecies of production, from the dwarf plants of Lapland hich clothe the lofty mountain tops, to the aromatic pecies of Sumatra, which shed their odours at its base. his portion of Peru contains the sources of those vast ivers which traverse the whole continent of South merica, and are the greatest on the face of the globe. ut by far the largest, most beautiful, and most valu- ble part of the Peruvian territory, lies to the east of e Andes, commencing on the eastern declivity of the econd chain, and stretching to the confines of Brazil. n this vast region, a thousand sources of wealth lie uried, for the greater part of it may be said to be yet nknown, although the riches which it contains are mmense. In fertility, luxuriance, and variety of vege- tion, it rivals Brazil, and the world does not present s with any higher standard of comparison. Every sort f production which springs from the ground may be ised in one part of Peru or another in the amplest undance. Its mineral treasures are gold, silver, latina, tin, copper, lead, quicksilver, precious stones, lt, alum, saltpetre, coal, sulphur, and others. The ost valuable of these are in great plenty.

Peru carries on considerable trade with Great Bri- in, the United States, France, the kindred repub- cs of South America, and other places. A treaty of mity, commerce, and navigation, with Great Britain, as signed at Lima on the 5th of June, 1837; by which mpetual freedom of trade was established with the untries of the Peruvio-Bolivian confederation. The ief articles of export are gold and silver, Peruvian rk, hides, nitre, sugar (unrefined), cotton, and sheeps' ol, tin, molasses, pot and pearl ashes, &c. The im- rts into Peru from Great Britain, chiefly of manu- tured goods, amounted, in 1833, to £387,524. In 34, the imports fell, on account of political agitations, t they have since risen, and on an average of years e steadily increasing. In 1835, they amounted to 41,324. The exports to the United States, in 1835, ounted to 1,118,278 dollars; those to France and her places were likewise considerable. The present venue of Peru has been estimated at £1,250,000; the penditure at a little less than that sum; and the tional debt at £6,000,000. But precise information these points is not to be obtained. There is a stand- g army of 3000 men maintained in Peru, and 2000 Bolivia, according to the articles of confederation. e religion of the republic is the Roman Catholic, no her being tolerated. Slavery has been long abolished ; but the state of the country in regard to edu- n and morals, is still very low. The total popu- n of Peru in 1838, was estimated at 1,700,000, sisting of three original castes—Spaniards, Indians, Negroes, and all their possible combinations. Lima, capital, which was formerly the grand entrepôt for trade of all the west coast of South America, con- s a population of 70,000. All the trade is carried at Callao, which, although six miles distant, is the rt of Lima. The next most important place is Cuzco, chief town of the interior, and the ancient capital the incas. Here are some magnificent remains of former riches and splendour of Peru, particularly Temple of the Sun, the wealth of which, when first iled by the Spaniards, was almost incalculable. The membrance of the ancient heathen worship is still served by an honorary institution, called the "Order the Sun." Besides Lima and Cusco, the next largest wn is the maritime port of Arequipa, which has been x times destroyed by eruptions from a neighbouring untain, and yet possessed a population of 40,000, vious to the revolution. There are also a great ny other towns of minor importance. Earthquakes e frequent in Peru. The city of Lima has been three es almost entirely destroyed by these visitations— 1687, 1746, and 1828.

BOLIVIA.

After independence was established in 1825, this portion of the ancient viceroyalty of Buenos Ayres received the name which it now bears, conferred in honour of the liberator, General Bolivar. A constitution, drawn up chiefly by Bolivar, and called the Bolivian Code, was immediately introduced, and for two years the republic was tranquil under the presidency of General Sucre. But when the great *libertador* became unpopular in his own country, and those troubles arose which darkened the close of his career, his constitution was rejected from Bolivia, the president was deposed, and Santa Cruz was elevated to the dignity. The present position of this republic we have already spoken of under Peru.

Bolivia is bounded on the north by Peru and Brazil, on the east by Brazil, on the south by the Buenos Ayrean provinces and Chili, and on the west by the Pacific Ocean and Peru. It comprehends a space of 480,000 square miles, and the population is estimated at 1,200,000, of whom probably two-thirds are Indians. This republic includes five of the provinces which were formerly under the Buenos Ayrean viceroyalty, but has been divided by the new government into six departments, namely, Potosi, Chuquisaca, La Paz, Santa Cruz, Cochabamba, and Oruro. The greater part of Bolivia is situated at a very high elevation, but towards the east it stretches down in extensive plains towards Brazil. The climate, therefore, is extremely various. On the high parts, snow-storms and hurricanes frequently prevail, and the plains, from the rigour of the weather, are nearly destitute of vegetation. The climate of Potosi, at an average elevation of 13,400 feet, is so changeable, that it frequently exhibits in one day all the vicissitudes of the four seasons of the year. Thence descending through the regions of Oruro, at an elevation of 12,400 feet, La Paz at 12,100, Chuquisaca at 9300, Cochabamba at 8400, down to the plains of Majos and Chiquitos, all the known degrees of temperature, from extreme cold to extreme heat, are experienced. This elevated region is enriched with the most valuable mines of gold and silver, which, with other precious metals, form the only articles of Bolivian commerce. The mountain of Illumini, in La Paz, which is supposed to contain rich veins of gold ore, is 24,000 feet above the level of the sea. From the great difficulty of working the mines, and the expense of extracting the ore, the greater part of the gold of Bolivia is obtained from the *lavaderos*, or gold washings in the beds of rivulets, where it is found in the shape of grains. The most productive of these *lavaderos* are those of Tipuani, in the province of Larecaja. Silver, however, is the great staple metallic production of Bolivia; and the famous mountain of Potosi is ranked next in importance to the mines of Guanaxuata in Mexico. On account of the inconsiderable nature of the rivers flowing from Bolivia to the Pacific, and the badness of the roads, it is impossible this country can enjoy much commerce with the Pacific; but towards the east, several large streams communicate with the great navigable rivers that flow into the Atlantic Ocean. The river Paro, or Beni, which rises near La Paz, and the Guapey, which rises near Cochabamba, after a long sweep, unite with the Mamori, and, flowing to the north-east, mingle with the waters of the Maranon or Amazon. The Picomayo, again, which rises near Potosi and Chuquisaca, and the Vermejo, which rises in the valley of Tareja, flow to the south-east, and mingle with the Paraguay, the upper part of the mighty Rio de La Plata. All these rivers are navigable almost to their source, and, with steam navigation, would open up a direct communication between these rich districts and the nations of Europe.

The table land of Titicaca is the most elevated on the globe, with the exception of that of Thibet; but while the latter only presents pastures and flocks of sheep, the former exhibits towns and populous cities, and is covered with fine crops of wheat, barley, rye, &c. The lake of Titicaca is 12,700 feet above the level of the sea, and is twenty times the size of the lake of Geneva. It contains several islands, the largest of which, named Titicaca, is the place whence Manco Capac, and his

wife Manco Oello Huaco, were represented by Peruvian tradition to have come forth to found the empire of the incas, and spread civilisation, industry, and good government through the nations. A magnificent and gorgeous Temple of the Sun was afterwards erected here, the whole ornaments and wealth of which are said to have been thrown into the lake, to prevent their falling into the hands of the Spaniards.

COLOMBIA, OR THE REPUBLICS OF VENEZUELA, NEW GRANADA, AND QUITO.

For three years after the establishment of independence in Colombia, the country remained tranquil, Santander being vice-president, and exercising executive power in Bolivar's absence. The Peruvians had elected the latter president for life, and adopted his celebrated code; but as he belonged to Colombia, and as symptoms of rebellion had become apparent in that country, he resolved on relinquishing all the honours which the Peruvians were desirous of conferring on him, and returning to his native country. He arrived towards the close of 1826, from which period till his death in 1830, Colombia was a scene of turmoil and bloodshed. The person who played the most conspicuous part in this tumultuous drama, besides Bolivar himself, was General Paez, who had been appointed to the command of Venezuela. He gave great offence by his arbitrary conduct, was impeached, but refused to make his appearance. Immediately thereafter, he placed himself at the head of a strong party opposed to the central system, and desirous of a separation from New Granada. Bolivar succeeded in quelling this insurrection of the north-eastern provinces, but the violence of parties again broke forth in 1828. The events which followed finally resulted in Bolivar's assuming absolute authority; from which period his popularity declined. Plots were formed to assassinate him, but all these attempts ended in the destruction of the projectors, and in Bolivar's exercising, probably to an unwarrantable extent, the absolute power which had been entrusted to him. In 1829, war was declared against Colombia by Peru. The causes of this are partly to be attributed to personal animosity, partly to national jealousy, partly to a desire to get possession of Guayaquil, one of the principal ports of the Colombian territory. The armies met at Tarqui, in Quito, when a sanguinary conflict took place, in which the Peruvians were defeated; and this, along with other circumstances, for a time raised the hopes of Bolivar and his friends. The great cause of difference between the dictator and the people was the Bolivian code or constitution, which did not, it was asserted, allow enough of liberty to the subject, the country being eminently republican and democratic in its views. The fact is, the people had become intoxicated with their freedom, and nothing short of licentiousness would satisfy them. But a civil war was prevented by the death of Bolivar, which took place on the 17th of December 1830. As soon as this event became known, the three component states of Colombia peaceably agreed to become independent of one another. The limits of these states are nearly the same as they were when each was a separate province subject to Spain. Their constitutions are based on the most liberal republican principles, and they are leagued together for mutual support against foreign aggression. The national debt of Colombia was equally divided amongst the three states in December 1834; slavery was for ever abolished in all of them; and, upon the whole, they are likely to go on much more peaceably and rationally apart, than if they were united under one head. We shall give a brief description of each state.

NEW GRENADA.

This republic is bounded on the north by the Caribbean Sea and Guatemala; on the east by Venezuela and Guiana; on the south by the Amazon and Quito; and on the west by the Pacific Ocean. The great chain of the Andes traverses this country, and the mountains are extremely rich in gold and silver; and there are also mines of platina, copper, lead, and emeralds. The value of gold and silver produced annually is stated at £650,000. It is divided into five districts and thirteen provinces, the united population of which, according to the census of 1835, amounts to 1,687,109; or, on account of errors, 1,700,000. Santa Fe de Rogota is the capital of the republic; it has a population of about 40,000. Here a national academy was opened in 1833. In 1833, the income amounted to 2,337,836 dollars, and the expenditure to 2,211,554 dollars; leaving a balance of 126,282 dollars for payment of the interest of the national debt. The share which fell to New Granada was above £3,000,000. The principal articles of export are cacoa, indigo, tobacco, coffee, hides, and cattle. The imports are manufactured goods of almost every description. What the value of these may be, it is impossible to say, for the contraband trade has been here carried on to an almost unparalleled extent.

VENEZUELA.

This state extends from the republic of Quito or the Equator to 12 degrees of north latitude, and from 60 degrees to 71 degrees 36 minutes of west longitude. On the north and east it is washed by the Atlantic Ocean, and has a number of good ports. The most remarkable feature of the country is the great river Orinoco. It is also traversed by the Andes; and the great lakes of Maracaybo and Valencia belong to its territory. The northern part is mountainous; but in the south, on the banks of the Orinoco, are immense planes, called *llanos*, the climate of which is hot, and in some parts unhealthy. The year is completely divided into the rainy and the dry seasons; the former commencing in November and ending in April. The productions are sugar, coffee, indigo, cotton, and tobacco. The plains on the Orinoco furnish extensive pastures, which support numerous herds of cattle. Venezuela is partitioned into four departments, and further divided into twelve provinces, which contain in all a population of 829,000. The budget for 1838 was estimated at 1,763,649 piastres. According to the division of the national debt already noticed, £1,941,705 fell to the share of Venezuela. The patronage of the church has been taken from the archbishop of Caracas, and is now in the hands of the president. Tithes are abolished, the clergy being paid by the state. Monastic institutions and missions have been done away with, their income and possessions being applied to the uses of the National College established at Maracaybo for public instruction. The principal towns of Venezuela are Caracas, with a population of probably 40,000; Cumana, a sea-port, with 25,000 inhabitants; Varinas, with 12,000; and Maracaybo, situated on the margin of the great lake of the same name, which has 25,000 inhabitants. The cultivation of the soil and the rearing of cattle, are the great objects of industry in this republic. With the overplus of these, the inhabitants obtain the manufactures of Europe. The chief articles of export are cocoa, coffee, sugar, tobacco, cotton, hides, dye-woods, sarsaparilla, Peruvian bark, balsam, indigo, furs, &c. The imports are for the most part the fabrics of England and France. It is difficult to state with certainty what the exports and imports may amount to respectively, but the former may be estimated at 2,000,000, and the latter at 4,000,000 of piastres. (A piastre is equal to 4s. 3¾d. sterling.)

EQUATOR, OR QUITO.

The territory of the Equator comprehends the ancient presidency of Quito, extending from 2 degrees of north to 6 degrees of south latitude, and from 76 degrees 30 minutes to 80 degrees 40 minutes of west longitude. On the south it borders on Peru and Brazil, the latter country forming also its eastern boundary; on the north its limits are New Granada, and it is washed by the Pacific Ocean on the west. This republic is intersected by both chains of the Andes, and consequently presents great diversity of surface and climate.

very thing done to promote education and indus-
In 1815, also, Brazil was created an independent
although annexed to the crown of Portugal. In
some democratic insurrections broke out in Per-
nco; and although suppressed, discontent still
ued, until in 1821 it was announced that the
guese constitution was to be conferred on Brazil.
e this, however, King Joam had sailed for Por-
, promising at his departure increased pay to all
ficers and soldiers. But when he was gone, it was
he had carried off every farthing that was in the
ury, having also raised immense sums by means of
ury bills. The public indignation at this discovery,
her with the suspicion that he intended again to
e Brazil to the condition of a vice-royalty, occa-
d a general call for his son Don Pedro, who had
left as regent, to become the head of the govern-
as an independent state. This he readily complied
In 1822, he was proclaimed emperor; and in
his title and the independence of Brazil were ac-
ledged by his father. Then followed the war with
os Ayres respecting the Banda Oriental, which, at
rmination in 1828, left the country destitute of all
ney but paper. This excited much discontent,
t the same time, the abolition of the Portuguese
itution by Miguel excited the suspicions of the
ilians that that event was only the prelude to a
ar occurrence in Brazil; nor did the language and
rtment of Pedro tend at all to allay their fears. In
1830, the nation had become divided into consti-
nalists (Brazilians) and absolutists (Portuguese);
n attempt having failed to induce the troops to
re the emperor absolute, he to all appearance
d the constitutionalists. His measures and con-
however, continued so equivocal, that, in March
, manifestations of popular excitement broke out.
extreme rigour he exercised on this occasion, and
ubsequent vacillation, increased and incensed his
ies more and more; and in the April following,
rbances broke out in which many persons were
l. Pedro immediately announced a change of mi-
y; the public remonstrated against this, but he
ined resolute; an insurrection, in which the troops
d, was the consequence; and next morning Pedro
ated in favour of his infant son, Pedro II., and
rked from Rio Janeiro, on board an English ship
ar, carrying with him an immense treasure in dia-
ds and jewels. A permanent regency was appointed
anage the government during the minority of the
ror; but political storms have not ceased to "lower
this house." Insurrections are by no means un-
non in Brazil; some recent inroads of the Indian
s have been attended with much loss of life and
erty. The city of Para was taken in 1836, but
wards evacuated. Bahia was likewise captured by
el army of Indians and others, but wrested from
by the imperial troops with a great loss on both
. This event occurred so late as March 1838. A
us insurrection has recently broken out in the pro-
e of Rio Grande. The imperial troops were repeat-
defeated, and that portion of the country has
ared its independence. That this will be main-
d, is quite uncertain.

o describe minutely the physical characteristics of
ast a region as that of Brazil, would carry us far
nd our limits. Generally speaking, there is not
he globe a finer country, one blessed with a more
al climate, or a more fertile soil; more happily
rsified with wood and water, or with abundance of
gable rivers; or more famed for its produce of
and diamonds. Nearly the whole of the most
ly valued productions of the earth are raised within
erritory. The land rises by gentle gradations from
shore to the interior, to the height of from three
ix thousand feet above the level of the sea. At
elevation within the tropics, the climate is tempe-
, and European fruits and grains are raised in
dance. The intervening valleys have a warmer
perature, and consequently are extremely favour-

tains are in some parts covered with forests, high and abrupt in appearance, and difficult of access. On the other side the hills rise with a gentle acclivity, and are separated from each other by vales, the vegetation of which is described as extremely beautiful. The view of the island from the sea has been long celebrated for its splendour; the mountains sometimes appearing above the clouds, and studded with forests. The great savannahs or plains are covered with the most beautiful pasture, woods, and all the magnificent vegetation of the tropics. The mountains in some parts reach a great height; Blue Mountain Peak being 7770 feet above the level of the sea; Portland Gap Ridge 6501; Catherine's Peak 4970; and others of a lesser elevation. Some authorities assert, that at the eastern part of the island, three peaks of the grand ridge of the Blue Mountains reach the heights of 8184, 7656, and 7576 feet above the level of the sea. The mountains are generally of a conical form, very steep, and approaching on the north side very near to the sea. The deep ravines between the lofty mountains are densely covered with woods, and are denominated cockpits. These offer a striking contrast to the lower mountains, where the coffee-plant, pimento, cotton, &c., are cultivated. On the south side, the mountains are situated a little distant from the sea, leaving plains of about twelve miles wide.

There are numerous rivers in Jamaica, two hundred of which have been enumerated; but none, owing to the irregular nature of the country, are navigable for vessels of any burden. Black river is the largest; and running through a flat country, is navigable for vessels of small tonnage for about thirty miles. The only other rivers of any note are the Rio Cobre and Rio Minho on the south; and the Marthabrae, White, Ginger, and Great River on the north side. These rivers are extremely valuable in the cultivation of the soil, the great height from which the water runs allowing it to be carried a considerable length in irrigating the country, and turning mills upon plantations. The rapidity of the current also prevents it from stagnating; and thus it is kept pure for animals to drink, from its source to the ocean. There are numerous springs and rivulets throughout the country, several of which are of a medicinal nature. Two sulphureous springs, one hot and the other cold, are very celebrated, and exceedingly beneficial in cutaneous diseases. There are sixteen principal harbours, which afford secure havens for shipping, and thirty bays or roads with good anchorage.

The soil of the country is generally deep and fertile, presenting a shining appearance to the eye when first turned up. In some parts it is of a chocolate colour, in others a bright yellow, and even scarlet. The best soil for cultivation is what is termed the brick mould, which is of great depth, so rich as to require no manure, and of a quality which seems well suited for the climate. It is so far retentive, that in dry weather it retains enough of moisture for the preservation of the plants, and so porous as to admit of the superfluous water sinking through it during heavy rains. This soil is composed of clay, sand, and black mould, and is thought the best soil in the island for the cultivation of the sugar-cane. The next soil in point of fertility is the black shell mould; and there are many varieties throughout the island, all more or less fitted for cultivation. Silver and gold mica frequently occur in the soil, and the latter is sometimes mistaken for gold dust. No gold has ever been discovered, however, although it is certain that the natives were possessed of plenty when the Spaniards first visited the island. A rich lead ore is found in some parts of the country, which is impregnated with silver. This ore is worked at Liguana; and varieties of copper, striated antimony, and iron-stone, have also been obtained in some parts of the island. White freestone, quartz, limestone, and a species of bastard marble, also occur in considerable quantities.

Jamaica is divided into three counties, Middlesex, Surrey, and Cornwall. Middlesex is divided into nine parishes, Surrey into seven, and Cornwall into five. The seat of government is Spanish Town, in the co Middlesex, situated at the extremity of an ex plain. The mountains closely approach the to the river Cobre runs past it, at the distance of quarter of a mile. The town is not large, but th ings are very magnificent, being built in the Spanish architecture. The finest building is th nor's residence, called King's House, which one whole side of a quadrangle. Kingston is important town in the island, and is generally c as the capital, although not nominally so. It i upon a gentle inclined plain, which is enclos north by the Liguana ridge of mountains. Th tains form a sort of semicircle, and the plain down to the harbour, which is amongst the fi world. It affords excellent anchorage all r the largest merchant ships can ride close in sl harbour is defended by numerous batteries, a sidered perfectly unassailable from the sea. T of Kingston are built with the greatest somewhat in the style of the New Town of E The houses are principally of wood, and, two storeys high, with verandas above and b English and Scotch churches are very elegant particularly the former. It contains about habitants, of whom 12,000 are whites, an people of colour. There are excellent m butcher meat, fish, and vegetables of every d On a plain at the top of the declivity on whic is situated, stands a fine range of barracks, Park Camp. This camp is situated about tw feet above the level of the sea, and is capable modating upwards of twelve hundred men. an excellent hospital attached to the barra bath, which, only four feet deep, is capable ing 70,000 gallons of running water. Mon situated on the opposite side of the island fr ton, is a seaport of some importance. It foot of a range of mountains which nearly the town, and possesses a neat church and co barracks. Falmouth is situated about fifteen of Montego, and is rising rapidly to importa harbour in the inside is deep and well shel the entrance is intricate, and not more than feet deep across the bar. The town is built o side of the harbour, and possesses several g offices, a free school, and commodious barrac is more produce shipped from this port than other in the island after Kingston. Savanna is a fine healthy military station, situated moreland parish. The town is built upon t the harbour of which is good, and the bar situated about a mile from the town, in the highly cultivated country.

The government of Jamaica consists of a a council of twelve, and a house of assem governor has the chief civil and military auth he holds his appointment from the home gov The members of the council are selected from the justices of the peace by the queen; the li governor, attorney-general, and bishop, being by right of the offices they hold. The house bly consists of forty-five members, two being each parish, and one additional from each of of Kingston, Spanish Town, and Port Royal. also a supreme court, an assize court, a cour mon pleas, which sit at stated times for the pu of crime. The military force of the island c about three thousand regular troops, some of people of colour; and the militia force, which to from sixteen to eighteen thousand men. males, from the age of fifteen to sixty, are enlist in the militia service, and no substi allowed.

II.—TRINIDAD.

This island, the next in importance to Ja the British West India possessions, is favour ated at the mouths of the large river Orinoco.

was declared; in others, more gradually. In some
s, as in the Brazils and Guiana, slavery still exists;
the spirit of all the various governments is favour-
to manumission, and universal freedom seems to
matter neither improbable nor distant. The uniform
blishment of the Roman Catholic religion through-
all the states, has also, no doubt, contributed much
roduce a community of feeling and sentiment among
lasses of the population, all being alike—negro as
as white—members of the church. The events of
revolution were naturally accompanied with feel-
of jealousy respecting all the original institutions
oduced by the Spaniards, religious as well as civil;
in the matter of religion, the odium seems to have
n not on the church, but on the priesthood. This
more especially the case in the commercial cities,
lmost all of which an complete an overturn and
iation took place among the rich and indolent esta-
lments of monks and friars, as during the period
e reformation in Scotland.

enerally speaking, the natives of South America
a much more active and industrious race of men
the creoles of other tropical countries. The Spa-
custom of the *siesta*, or noon-sleep, is universally
ralent; but both before and after that period of
se, they are actively engaged either in transacting
ness, or in giving and receiving visits, attending
lic exhibitions, promenading, making short journeys
leasure, &c. As amongst the whites in the West
ies, universal hospitality prevails, every man's house
g a home to the traveller; and this is the more
ssary from the scarcity and bad provisions of the
. The manners of the inn-keepers and their ser-
ts resemble those in the United States, where both
down at table, and converse familiarly with their
omers. The staple dish throughout South America,
at inns and in private houses, is the *olla*, consisting
oiled or stewed beef, covered with *friolas* and other
etables. In these places of refreshment, too, tra-
ers of all ranks and characters dine at the same
rd, and take their siesta in the same room, upon
s spread down for the purpose. Travellers of
pectability generally endeavour, however, to stop at
houses of proprietors near the wayside, who live in
yle of wealthy ease and luxury.

he Spanish amusement of bull-baiting is pursued
great avidity by the South Americans. But per-
s a more demoralising and pernicious amusement
he besetting vice of gambling, in which all classes
he towns indulge to a great extent. The method
atching the wild cattle that rove in immense herds
r the *pampas*, is a practice altogether peculiar to the
th Americans. The instrument used is called a lasso,
n the Spanish *laso*, signifying slip-knot or noose, and
operation of using it is called lassoing. It consists
rope made of strips of untanned hide, varying in
gth from fifteen to twenty yards, and is about as thick
he little finger. It has a noose or running-knot at
end, the other extremity being fastened by an eye
button to a ring in a strong hide-belt or surcingle,
nd tightly round the horse. The coil is grasped by
horseman's left hand, while the noose, which is held
he right, trails along the ground, except when in use,
then it is whirled round the head with considerable
city, during which, by a peculiar turn of the wrist,
made to assume a circular form; so that, when
vered from the hand, the noose preserves itself open
it falls over the object at which it has been aimed.

Wild horses are captured with what is called, in the
guage of the Gaucho, "las bolas," or balls—a most
midable weapon in the hands of him who knows how
se it. It consists of three thongs or cords of hide,
h more than a yard long, having balls attached to
extremities. The "boleador," or he who is going
ling the balls, takes one ball in his hand, and swing-
the others rapidly round his head, throws "las
as" with all his might, and unerring certainty,
nd the hind legs of his victim, which immediately
es to the ground.

V.—ST VINCENT AND ITS DEPENDENCIES.

This is thought the most beautiful of the Carribean islands; it was discovered by Columbus in 1498. It is about twenty-four miles long and twenty broad; fifty-five miles west of Barbadoes, and about the same distance from Grenada. This island was first settled by the French; captured by the British, and retaken; but finally ceded to this country in 1783. Its character is decidedly volcanic, traces of strata which have undergone the action of fire being every where visible. The mountains are high and sharp at the top, running from north to south, with deep valleys between. The soil is of a strong loam in the valleys, but assumes a more sandy nature on the hilly ground. In 1812, St Vincent was visited by a severe volcanic eruption, the matter from which nearly covered the whole surface of the island; some particles even reached Barbadoes; and the noise was heard for three hundred miles. The damage done to the island was not great, but fifty persons lost their lives on the occasion. The island is divided into five parishes, of which the principal is St George, in which the capital, Kingston, is situated. The houses of the town are built of stone in the lower storeys and wood in the upper; and there are many commodious public buildings, but none of them of any great elegance. There is a famous botanic garden about one mile from Kingston, occupying about thirty acres of ground, and containing a fine collection of tropical plants. The most celebrated object in this island is the Souffriere, a volcano, the crater of which is three miles in circumference, and five hundred feet in depth. The climate is thought very healthy; but hurricanes are frequent, and sometimes very destructive. This island is governed much in the same manner as Grenada. There are eight small islands adjoining to St Vincent, which are cultivated; but they are not of such importance as to warrant particular mention.

VI.—BARBADOES.

This is the most easterly of the Carribean islands, and was the first settlement made by the British in the West Indies. It is about twenty-two miles in length and fourteen in breadth, containing an area of 106,470 acres. The period of the discovery of this island is unknown, the first mention made of it being in 1600. It was colonised by the British in 1625, Charles I. having made a grant of it to the Earl of Carlisle, who encouraged emigration to the island. A society of London merchants accepted of 10,000 acres on certain conditions, and sent out a governor of their own. After this the settlers increased very rapidly; and in 1650 it was computed that there were upwards of twenty thousand British in the island. During the Commonwealth, an armament was fitted out by Cromwell against Barbadoes, for adhering to the royal cause, which committed great depredations against the inhabitants; and since this time the population has rather decreased. The island is generally level, except in the north-east quarter, and here, in some parts, the hills reach the height of 1100 feet. It has a beautiful appearance, from the land being well cultivated and the vegetation luxuriant. The soil is good, varying from a rich deep mould to a light sand, and a red clay of considerable depth is occasionally found. There are a number of springs in the island, one of which casts up a bituminous matter called Barbadoes tar, and another emits a stream of sulphuretted hydrogen gas, which can be ignited. Oxen, horses, and other cattle, are plentiful, the first being most generally used for labour. Considerable numbers of hogs and poultry are reared; and, indeed, this island is distinguished from most of the West India colonies by the quantity of provisions which are raised, the inhabitants depending little upon foreign supplies. Plovers, curlews, wild-duck, teal, and other water game, frequent the coast in great numbers, and *afford an agreeable article of food.*

Barbadoes is divided into five districts and eleven *parishes, and contains* four towns. Bridgetown, the capital, is situated on the shores of Carlisle Bay contains about twenty thousand houses. The t well laid out, many of the houses are very hand and spacious barracks occupy the southern extr The climate is considered healthy, but would fe tremely hot were it not for the constant trade- The island is subject to hurricanes, one of wh 1780, laid waste its whole extent. The loss o on this melancholy occasion was estimated at thousand, and property valued at upwards of a m was destroyed. The island is ruled by a gover council, and house of representatives. The pow the governor are entirely negative, he being on titled to recommend measures to the assembly, they may either adopt or reject. Barbadoes see have reached the height of its prosperity at the the seventeenth century, and since that time the lation has in some measure decreased. In 167 white population was estimated at 50,000, and the at 100,000, while at present the whole populatio not exceed 90,000.

VII.—ST LUCIA.

This island is situated in latitude 13° 50′ nort longitude 60° 58′ west. It is about thirty-two long and twelve broad. The English were the fir made a settlement in this island, but the colonists completely destroyed by the natives. It was settled, and since that time has passed repeatedly the British to the French, until 1803, when it wa tured by the British, in whose possession it has since remained. This island is traversed longitudi or from north to south, by a ridge of lofty moun which terminate in most fantastic sharp points. mountains are densely wooded, and at times, from t traction of the trees, are completely enveloped in a The approach to the island from the south is ve markable. Two rocks, called the Sugar-Loaves perpendicularly out of the sea, tapering away to the summit. These rocks are covered with vege and stand at each side of the entrance to a bea bay. On the west coast, there is an excellent ha called the Little Careenage, which, admitting on ship at a time, is capable of containing thirty sh the line. The island is divided into Basseterr low or leeward country, which is the best cult district, and Capisterre, the high country. B these districts are considered unhealthy, the first the abundance of stagnant water, and the other the denseness of the woods. As cultivation pro however, these causes will be removed, and the rendered as healthy as any in its neighbourhood. capital is Castries, which is the only town in the i and a place of no importance. There is a small called Pigeon Island, about six miles from St which is considered a healthy and important m station; and there is excellent anchorage grou tween it and St Lucia.

VIII.—DOMINICA.

This island is situated between the French c of Martinique and Guadaloupe, in 15° 25′ north la and 61° 15′ west longitude. It is about twent miles in length and sixteen in breadth, containing 186,436 acres. It was considered a neutral islan 1759, when it was taken possession of by the E with whom, after being repeatedly taken and re the island still remains. Dominica is of volcanic and has many lofty mountains, the highest of wh 5314 feet above the sea's level. Several of these tains contain active volcanoes, which frequent charge vast quantities of burning sulphur; and th many hot water springs throughout the island. valleys are fertile, well watered with thirty fine and numerous smaller streams. The trees are affording the finest timber, such as locust-wood wood, mastic, iron-wood, cinnamon, bastard mah and a gum tree of considerable value. The fer

the island is not subjected to either heavy dews or ere hurricanes, like most of the other islands. An- a is ruled by a governor, who is also commander- chief over Montserrat, Barbuda, Anguilla, St Chris- her's, Nevis, the Virgin Islands, and Dominica; with gislative council, and house of assembly. There are teen free schools in the island, which afford instruc- n to 1216 scholars; and religious instruction is admi- tered with great care by all sects. Antigua was the t island to ameliorate the slave laws, by affording the used the benefit of trial by jury; and an act of as- bly, 15th February 1834, decreed the emancipation every slave, without requiring the period of appren- ship prescribed by parliament.

XI.—ST CHRISTOPHER'S OR ST KITT'S.

This island, situated in latitude 17° 10' and longitude ° 40', is seventy-two miles in circumference, and con- ns sixty-eight square miles. It was discovered by lumbus, who is said to have given it his own name; d it was first settled by an Englishman of the name Warner and fourteen associates. Warner found veral Frenchmen already on the island; and these o parties, after making war upon the natives, divided island between them, one part, called Capisterre, or h country, being assigned to the French, and the er part, called Basseterre, or low country, given to English. Many bloody battles were fought between se two parties until 1713, when the whole island was ded to Britain. St Christopher's is of an irregular long shape, divided from north to south by a ridge mountains; and the whole land of the island is some- at elevated, sloping gradually from the centre to the s. The greatest height is Mount Misery, which rises 11 feet, almost perpendicularly, and is clothed with getation nearly to the summit. There is no plain in e island which can be called swampy, the gradual fall the ground carrying off any superfluous moisture m the earth. The vale of Basseterre is described as tremely beautiful, the ground being very rich, and ery where highly cultivated. The soil is chiefly of a rk grey loam, lying upon a bed of ashes, very porous, d is considered the finest soil for the cultivation of e sugar-cane in the West Indies. There is said to a sulphur mine in one of the mountains of the centre, d another of silver; but it does not appear that these ve ever been worked. The island is watered by four vers, none of them of any size; and there are nume- us springs in the low lands. These, however, from rong saline impregnations, are not fit for drinking, d the inhabitants have to collect rain water in tanks r domestic purposes. This island is extremely dry d healthy, the rains being more frequent than heavy, d the nature of the land preventing the water from agnating. The capital is Basseterre, which is the best hipping station. The government consists of a lieute- ant-governor, council, and house of assembly; and e colonists have always shown a desire to promote ducation.

XII.—NEVIS.

This beautiful little island, consisting only of a single ountain, which rises like a cone out of the sea, green, nbroken, and verdant to the summit, was discovered y Columbus at the same time with St Christopher's, om which it is separated by a channel about two miles road. It was first taken possession of by a party of nglish from St Christopher's; and the population is id to have rapidly increased. The mountain of which evis is composed is about four miles in length, and ree in breadth; its area being about twenty square iles. The summit has the appearance of a crater. he hill is well cultivated; and at the height where ultivation ceases, evergreen forest-trees grow luxuri- ntly, the whole island having a cheerful, picturesque spect. It is divided into five parishes, with three good oadsteads. The capital is Charlestown, which is de- cribed as a neat well-built town, with several hand- ome public edifices. The government consists of a

council and assembly, subject in certain matters to the government of St Christopher's.

XIII.—BARBUDA AND ANGUILLA.

These two islands, although far separated, may properly be classed together, from the similarity of their scenery and the occupations of the inhabitants. Barbuda is situated about twenty miles north-east of St Christopher's, and ten north of Antigua. It is about twenty miles long and twelve broad. The first notice made of Barbuda is in the time of Queen Anne, when it was given in perpetual grant to General Codrington and his descendants, by whom the greater portion of it is still possessed. Anguilla, or Snake Island, is about 100 miles north of Barbuda, and the same distance north-north-west of St Christopher's, situated in latitude 18° north, and longitude 64° west. It is thirty miles long and three broad, and receives its name (signifying an *eel*) from the peculiarly winding shape it presents. These islands were both first settled by the British; and, although subject to occasional attacks from other powers, they have always remained in the possession of this country.

The interior aspect of these two islands is quite different from that of any of our other West Indian settlements, being in many respects, indeed, quite *English*. The sole occupation of the inhabitants is farming, rearing stock, and cultivating provisions, for which a ready market is found in the neighbouring islands. There are no groups of masts in the bays and harbours; and instead of the laborious bustle, smoke, and noise, incidental to the sugar and coffee plantations, there are to be seen only numerous little rural dwellings, surrounded by waving crops of grain, and verdant fields covered with sheep and cattle.

XIV.—VIRGIN ISLANDS.

This name was given by the discoverer Columbus (in 1493) to a group of about forty small islands, lying to the northward of the Leeward Carribean Islands, and between them and Puerto (or Porto) Rico. They extend about twenty-four leagues from east to west, and about sixteen from north to south. They are divided between the British, Danes, and Spaniards, but much the larger and more valuable number belong to the former. The names of these are Tortola, Virgin Gorda (or Penniston, and sometimes corrupted into *Spanish Town*), Josvan Dykes, Guana Isle, Beef and Thatch Islands, Anegada, Nichar, Prickly Pear, Camanas, Ginger, Cooper's, Salt Island, St Peter's Island, and several others of little or no value. Those belonging to the Danes and Spaniards will be noticed in their proper places.

The British Virgin Islands were first possessed by a party of Dutch buccaneers, who built a fort on Tortola, but they were expelled soon after by a party of English. They have remained in the possession of this country ever since. The largest of these islands is Anegada, the next Tortola; and although never considered of any great importance, they afforded excellent shelter to shipping during the late war. Tortola is mountainous, the interior containing large tracts of waste land difficult of access. The soil is thin, and not well suited to the cultivation of the sugar-cane, although this and cotton are the chief articles of produce. The harbour of Tortola is very extensive, completely landlocked, and has afforded shelter, in many cases during the war, to 400 vessels. Anegada, although the largest island in extent, is of little importance, only a very small portion of it being under cultivation. It is surrounded by a reef which renders it difficult of access, and the other islands being so near, it is little frequented. Virgin Gorda is of an irregular shape, and contains two good bays, where ships may ride in perfect security. The soil is of a light sandy nature, and the chief articles of produce are sugar, indigo, tobacco, and cotton. These islands were formerly ruled by a deputy-governor and *council, who exercised both* the legislative and executive *authority, but they are now* subject to the government of St Christopher's, with a council and assembly of their own.

XV.—THE BAHAMAS OR LUCAYOS ISLANDS.

These are the most northerly of all the West India islands, stretching towards the coast of Florida, and forming with it the channel called the Strait of Florida. They were the first land discovered by Columbus in 1492, and amount in number to fully five hundred. The island which gives the name to the whole is the most northern, as well as the most important of the group. A settlement was established by the British in 16[illegible], which was ravaged by the French and Spaniards several times, and the group of islands became a nest for pirates, until the beginning of the last century, when they were expelled by the British. The Bahamas are evidently of coral formation, and although flat, they have a very pleasing aspect, from the richness of the vegetation. The chief island is New Providence, which contains the capital Nassau. These islands are very healthy, and from their situation the climate is delightful, being of a medium temperature. The chief article produced for exportation is cotton, neither sugar nor coffee having succeeded. Provisions of all sorts are very plentiful, cattle and sheep thrive well, and the shores abound with fish and turtle. The government consists of a governor, council, and house of assembly.

XVI.—BERMUDAS, OR SOMER ISLANDS.

These are a small cluster of islands, lying almost in the shape of a shepherd's crook, in latitude 32° 20′, and longitude 64° 50′, distant about six hundred miles from the nearest point of the American continent. Their discovery was owing to the shipwreck of Juan de Bermudez, a Spaniard, who was driven ashore upon these islands while on a voyage from Spain to Cuba. The same fate happened to Sir George Somers, an Englishman, in 1609, who was the first to colonise the Bermudas. They are upwards of three hundred in number, contain about fourteen thousand acres of land, and are so much alike in character, that to describe one is to describe the whole. The principal islands are St George, Ireland, St David, Somerset, Long and Birds' Islands, &c. These lie close together, in such a way as to form capacious bays, which afford good anchorage when once got into. The coast, however, is of the most dangerous description, being thickly studded with rocks, which are visible at low water, and disappear at flood tide. The chief articles of produce consist of arrow-root, coffee, cotton, and indigo. The cedar-tree grows to a great height, and is used for ship-building, and the palmetto is much cultivated for making straw hats. The soil is very fertile, and produces many kinds of vegetables fit for food; and medicinal plants, such as the aloe, jalap, &c., grow spontaneously. The whale is an annual visiter to the coast, the catching of which forms a lucrative employment to the inhabitants. Bermudas possesses no fresh water streams, and only a few wells, the water of which is brackish; but there are a great many tanks which fill during the rainy season, and supply the inhabitants. The climate is not considered healthy, the yellow fever being of frequent occurrence. Hurricanes visit the islands annually, the inhabitants being able to tell their approach by a halo round the moon. The Bermudas have never been considered of great importance to this country; but they are likely to become more so in consequence of their being formed into a penal settlement.

BRITISH GUIANA.

The British South American settlements, now forming the colony of Guiana, although not properly belonging to the West Indies, naturally come to be noticed here. This colony, as claimed by Britain, extends from the river Coventyn, in 56° 58′, to Punta Barima, at the southern outlet of the Orinoco, in 60° 6′ west longitude, in breadth, and from the Acaria mountains to the sea, in length. It formerly consisted of the settlements of Demerara, Essequibo, and Berbice, but these are now

s, the duragua, and the maam, which afford deli-
nd nutritious food. Land tortoises, and fresh-
turtles, are very abundant, the latter being chiefly
in the Essequibo and its tributaries. The rivers
ll stored with fish, some of which are very large,
id to be as delicate as any European fresh-water

The wild animals seldom attack man unless
ked, but they prove sometimes very destructive
flocks of the settlers. The serpents are all de-
d as sluggish and loath to bite, unless irritated;
atisfy themselves with attacking deer and smaller
ls. The inhabitants of Guiana are constantly
ed by the insects, which are very numerous, and
bite is painful, although not dangerous. The worst
se are the centipede, the scorpion, the bush spider,
igo, the mosquito; and some species of ants
very destructive to vegetation.

tish Guiana is divided into three counties, Demer-
Essequibo, and Berbice. The two former have
nited, and are divided into eleven parishes, and
tter into six. These colonies were first settled by
utch, captured by the British in 1796, given up to
atavian Republic in 1802, retaken in 1803, and
ceded to this country at the general peace of

The settlements are all situated upon the banks
rivers from which they receive their name, ex-
g along both sides, and generally as far inland as
vers are navigable. Each plantation has a wharf
ding-place of its own, and canals are cut into the
or the admission of boats and the draining of the
nding country. For fifty miles along the sea-
of the county of Berbice, a huge embankment has
nised against the sea, on which is a carriage-road
feet broad. A comparatively small portion of
a is yet cultivated, and an immense field for
al industry still lies open. The extent of culti-
land, however, is gradually increasing as the ad-
ges of the colony are becoming known. The staple
cts consist of sugar, rum, coffee, and cotton; and
thought, from the fertility of the soil, and the
ant summer which prevails, that many other valu-
plants might be cultivated. The climate is very
and regular throughout the year, the maximum
being 90, the minimum 74, and the mean tempera-
about 82 degrees. Two wet and two dry seasons
itute the changes of the year; the great wet season,
s called, commencing in the middle, and continuing
e end, of August, and the great dry season from the
f August till the end of November. The short wet
n occurs from December to the middle of February,
he short dry season from February to April. The
oing applies to the coast regions, the interior being
ed by only two great changes during the year.
icanes never occur in this colony, and even severe
are little known. Earthquakes are occasionally
ut they are very slight, and little attention is paid
em by the inhabitants.

e capital of British Guiana is George-town, situ-
on the western bank of the river Demerara, which
a population of from twenty to twenty-five thou-

The streets are generally wide, traversed by
s; the houses built of wood, two storeys high, and
ated from each other by gardens and ditches.
built in two rows, about a mile long, on the river
and contains several handsome buildings. New
erdam, the chief town in the county of Berbice,
ds about a mile and a half along the western
of the river Berbice. The houses have all gar-
behind, and are separated from each other by
s or trenches, and the town is described as pre-
ng a very pleasing aspect on entering the river.
population of this town, according to the last pub-
d census, was 2900, and there are many other vil-
which are gradually rising in importance.

e exports from Guiana, as is the case with all the
West India colonies, have decreased of late years,
from the encouragement which is now given to
rants, it is hoped that this will in the course of
be remedied. The exports from the whole of

Guiana in 1839 amounted to 35,845 hogsheads, 2135 tierces, 2396 barrels of sugar; 13,245 puncheons, 3817 hogsheads, 882 barrels of rum; 11,664 casks, 85 hogsheads, 14 barrels of molasses; 1,356,700 lbs. of coffee; 912 bales of cotton. The value of the imports in 1836 was £1,204,560, and since that period it is thought to have increased to nearly £1,500,000.*

The population of Guiana may be divided into Europeans, Africans, people of colour from other parts, and native Americans. The native Americans have dwindled down to a very small number, who lead a wandering life on the frontiers and savannahs of the colony.

The government is vested in a governor and court of policy, consisting of the governor, chief-justice, attorney-general, collector of customs, government secretary, and an equal number of persons elected from amongst the colonists. Formerly all free male inhabitants were liable to serve in a military capacity, but since the abolition of slavery the militia has been disbanded. The local government have made the greatest efforts to promote education in the colony, and many schools and churches have been erected, at considerable expense. The number of individuals who received instruction in 1838 amounted to 4683 adults, and 6680 children; making together 11,363.

GOVERNMENT OF THE BRITISH WEST INDIES.

The forms of government established in the British colonies in the West Indies, may be divided into two classes; those having a governor, council, and representative assembly; and those having only a governor and legislative council. The first includes Jamaica, Barbadoes, Antigua, Tobago, Grenada, St Vincent, Montserrat, Nevis, St Christopher's, Honduras, the Virgin Islands, the Bahamas, and the Bermudas; and the second, Guiana, Trinidad, and St Lucia. The reason for this difference is, that most of the colonies were acquired by conquest, and the inhabitants who chose to remain in the island were guaranteed their laws and the exercise of their religion. The governor has the chief civil and military authority; the council is somewhat analogous to the privy-council in this country, and the House of Assembly to the House of Commons. A member of the House of Assembly in Jamaica must possess a freehold of £300 per annum, or a personal estate of £3000; and an elector must have a freehold of £10 per annum in the parish for which he votes. Some of the islands have only lieutenant-governors, who are under the governor of some adjacent island. The lieutenant-governors of St Vincent, Grenada, Tobago, and Guiana, are under the governor of Barbadoes. Their powers, however, are nearly equal to those of a governor. In those islands which have no representative assembly, the legislative council consists of the chief secretary, the treasurer, the chief-justice, the attorney-general, and the commander of the troops. These are appointed by the crown; and sometimes a few of the principal landed proprietors are made members of the council. Several islands are sometimes included in one government, who send their representatives to the island which is the seat of legislature for the time being. Thus, in the Leeward Islands, St Christopher's, Nevis, Montserrat, and one or two other small islands, send their representatives to Antigua, which is the seat of government for them all; or, in other words, the residence of the governor. The superior and inferior courts of judicature resemble those in England, the laws being the same, unless as they may be affected by the special colonial enactments passed from time to time. Assize courts are frequently held, to expedite the course of justice. There are, likewise, parish courts, wherein justices of the peace decide summarily in small-debt cases. There are offices where all deeds, wills, sales, and patents, are recorded. All persons intending to leave the island are obliged to give notice at the *office of enrolment* three weeks before they can be entitled to a pass, or to find security for w they may leave unpaid in the island; and, fo precaution, masters of vessels are taken bou heavy penalties, not to carry off any perso such pass. The procedure of the assembly near as may be the formula of the British le and all their bills have the force of laws as s governor's assent is obtained. The power of however, is vested in the crown, but, *until re* laws are valid. The governor can also r assent to all such laws, and can dissolve an gether the assembly at pleasure. His salar partly by the crown, and partly from the venues.

* Schomburgk's Guiana.

FOREIGN POSSESSIONS.

FRENCH.

The French possessions in the West Indies the islands of Martinique, Guadaloupe, Marie and Deseada. Martinique is situated at the to the Gulf of Mexico, between the parallels and 14° 52′ north, and 63° 6′ and 63° 61′ w Paris. It is about fifty miles long and twen and a hundred and forty miles in circumference volcanic origin; romantic in appearance; and t tains are covered with almost impenetrabl Martinique is well watered, seventy fine rive enumerated; and there are many other strea island. The soil is good, although it varies account of the volcanic eruptions, which have places covered the surface of the land. Ab fifths of the whole island are cultivated; the re occupied with mountains, forests, and plains latter yield good herbage for cattle. Port Ro capital, is situated on one of the several bay indent the coast, and possesses the safest a capacious harbour in the West Indies. The well built, the streets regular, and running angles to each other, with a stream of water o side. The population is about 7000. The chi mercial town is St Pierre, which is described ceedingly neat. The houses are high, having pean aspect, and the streets regular and clean lation 30,000. The population of the whole i estimated at 101,865 inhabitants, of whom, 9937 were whites, 10,786 free people of colo 31,142 slaves.

Guadaloupe is situated in latitude 16° 20 and longitude 62° west. It is divided through th by a small channel, which is navigable for vessel tons, and forms as it were two islands. The division, called Grandeterre, is fourteen leagu and six broad; and the western, Basseterre, i leagues long and fourteen broad. There are volcanic mountains in Guadaloupe, one of wh emits smoke, and sometimes sparks of fire. Th is well watered, and diversified with hills and The soil is good, and yields abundance of fr grain. The chief productions are sugar, which, the cane reaches a great height, is not good; an which is also of an inferior description. Th is Pointe à Pitre, which possesses a spacious po here the principal trade is carried on. Bass also a considerable town, with many fine buildin tains, and public gardens.

Deseada and Marie Galante are small islan ated near Guadaloupe, and subject to its gove The former is famous for its cotton, and the latt sugar and coffee. These islands, along with Gua contain 334,142 English acres, with a popul 112,111 inhabitants.

SPANISH.

A few years ago, the colonial possessions extended from the frontiers of the United State to Cape Horn. Now, she has not a foot of lan whole American continent; and of the islands

DIES.

very dry, and the land parched. The climate of land is somewhat peculiar; on the north coast it rains during the whole year, while on the south an entire want of rain for twelve or fourteen is is no uncommon phenomenon. The chief pro- ns of Porto Rico are sugar, coffee, indigo, rice, ve-stock. The value of the exports in 1830 was ated at 5,411,342 dollars, and that of the imports 08,941 dollars; the dollar being equal to about shillings and threepence sterling. The number abitants in 1830 was estimated at 323,838, of 162,311 were whites. The chief towns are ques and Aguadilla.

DUTCH.

Dutch possessions in the West Indies are Cu- and St Eustatius, Saba, and part of St Martin— the Carribean group. The two former are natu- barren. Curaçoa, from its proximity to South ica, was formerly a place of great centraland ; but, since the independence of that continent, it used in a great measure to be an *entrepôt*. It is miles long and eleven broad, and produces sugar bacco. Like some of its sister isles, it is entirely dent on the rains for a supply of water. It was by the Spaniards until the year 1632, when it was by the Dutch, in whose hands it has since re- d. The population is estimated at about thirty and.

Eustatius consists of a single mountain, which is y-nine miles in circumference, and cultivated to ry summit. The productions are sugar and to- , and the population may be about fifteen thousand. first colonised by the Dutch in 1635, and con- d for many years a subject of contention between and the French, by whom it was alternately pos- d, until 1781, when it was captured by Admiral y. The booty which fell into the hands of the sh on this occasion was estimated at £4,000,000 ng. It was restored to the Dutch by the peace 95; and, after being again captured by the Eng- was finally secured to the Dutch by the peace of

a and St Martin are too inconsiderable to need r mention.

DANISH.

Danish settlements, all belonging to the Carri- group, are three in number—St Croix (or Santa , St Thomas, and St John, of which the former is of any importance. It is about eighty-one miles , and contains about thirty thousand inhabitants. oil is fertile and well cultivated, producing sugar, and tobacco. St Thomas is about six leagues in nference, and St John about the same. They are quite inconsiderable.

SWEDISH.

only colony belonging to the Swedes is the small d of St Bartholomew, in the leeward Carribean , and about fifteen miles in circumference. It nly one town and one harbour—Gustavia, and Le ange. The population is about six thousand.

INDEPENDENT ISLAND—ST DOMINGO.

is island, lying between Porto Rico on the east and ica and Cuba on the west, is three hundred and y miles long, and from sixty to one hundred and fifty broad. It was discovered by Columbus, who called paniola, or Little Spain, but the native inhabitants Hayti, or the mountainous land. The French Spaniards took possession of the island in 1630, ing it between them. No particular event took till the period of the French Revolution, when, g advantage of the contest between the royalists republicans, the natives and slaves rose in a body, acred the whites, and established their indepen- . Christophe, formerly a slave, was elected chief, governed the island with great wisdom for a num-

ber of years. In 1811, he was crowned king, created princes and nobles, and reigned undisputed till 1820, when his jealousy and despotism caused a general revolt, and, seeing his affairs desperate, he shot himself. A republic was then established, which was soon extended over the whole island, the Spanish half having also made a successful revolt. The government at present consists of a president, who is elected for life, and a senate and chamber of representatives.

The greater part of the coast of St Domingo is rocky and dangerous; but the bays of Samana and Neyba afford secure anchorage for large ships. There are also many small ports, situated generally at the mouths of rivers, in which small vessels can anchor with safety. The rivers are numerous, the principal being the Haina, the Nigua, the Neyba, and the Yima, which are navigable for some leagues from their entrance. In this island a salt-water lake exists, which is about eighteen leagues in circumference, and contains fish similar to those found in the sea, such as the shark, the seal, the porpoise, &c. The country is mountainous, but interspersed with fine plains of great fertility. The mountains intersect the island from east to west, some of them reaching the height of 6000 feet above the level of the sea. On the north-west side is an extensive plain, supposed to be eighty leagues long, and from ten to fifteen broad, which is extremely fertile, being watered by numerous streams. The soil is of the finest description, and is distinguished by the variety of its vegetable productions. The mahogany-tree grows to a great height, and the manchineel affords a species of wood veined like marble, and which is susceptible of the highest polish. Several species of dye-woods are found in the island, and also the lignum-vitæ, iron-wood, a species of oak of great size, and abundance of pine. The cotton-tree is the largest in the island, and is formed by the natives into canoes, which are light and capacious. The fruits are very numerous, and are described as extremely fine; and flowers of endless variety adorn the woods. The indigenous quadrupeds were only four in number, and they are now all extinct. The French and Spaniards, however, introduced breeds of horned cattle, hogs, sheep, horses, mules, and asses, which have multiplied exceedingly, and are of great value to the inhabitants. Wild-fowl are abundant; and turtle, and numerous varieties of fish, are caught on the coast and in the rivers. Mines of gold, silver, iron, and copper, were formerly found in this island, but it does not appear that they are worked to any extent at present. The island is divided into six districts, named generally from their positions, West, South, Antihonite, North, North-east, and South-east.

St Domingo was formerly considered one of the most important islands in the West Indies, and it is evident from its size, and the fertility of the soil, that it might be made so again. The policy of the government, since the independence of the island was declared, has been illiberal; heavy burdens are imposed upon merchants settling in the country, and all foreign merchandise is liable to a duty of 12 per cent. upon entering the country, except French, which pays 6 per cent. Sugar and coffee were formerly exported in very large quantities, but these have now very much decreased. In 1789, the amount of raw sugar exported was 93,500,000 French pounds, and in 1801 this had fallen off to 18,500,000. The export of coffee in 1789 was 76,835,219 pounds, and in 1801 this had decreased to 43,420,270 pounds. The exportation of wood has increased as that of sugar and coffee have declined, and tobacco is also more extensively cultivated. The population of the island has diminished considerably since the revolution. According to some accounts, it is estimated at 422,939, but others give it so high as 900,000. Port-au-Prince, the capital, is situated in the department of the West, has an excellent roadstead, and is the chief seat of trade. The town is built of wood; the streets are unpaved, and, from the marshy nature of the surrounding country, it is very unhealthy in summer. The population is about 15,000. The other towns are Port Haytien, which is the best built place in the island; Les Cayes, Domingo, the capital of what was formerly the S part of the island.

CLIMATE OF THE WEST INDIES.

The year may be divided into four seasons; first commencing with the mild vernal rains in or May, which usually last six weeks; the seco cludes June, July, August—hot and dry; the includes September, October, and November, are the hurricane and rainy months; and the December, January, February, and March, wh the most serene and cool months.

The climate of the West Indies is pretty near in all the islands. The average of the thermomete towns may be set down at 80 degrees during th mer months (from July to November). It often to above 90, but in the mountains it has been kn be so low as 44 degrees, so that a fire at noon i necessary a great part of the year. The temper kept cool by the alternations of the sea and land b the former blowing only during the day, the lat during the night. Of the latter, which alway from the centre of the island (be it ever so sm only scientific account ever given is that of Dr F which is as follows:—"As soon as the sea-bre away (in the afternoon), the air of the plains rarefied, ascends towards the tops of the mo and is there condensed by the cold, which, m specifically heavier than it was before, it descen to the plains on both sides of the ridge." It is a lar dispensation of Providence, that in Barbad the smaller windward Carribean islands, wh without these landward breezes, the sea-bre trade-wind) blows both night and day.

The most delightful time of day in Jamaica is dawn, before the sun has yet begun to pour hi gence over the hemisphere of the Carribees, and the land-breeze has died away. The sea-bre "doctor," as it is gratefully designated by the tants of Jamaica, which invariably blows from the east, or some other point ranging from south t generally sets in about nine o'clock A.M., at fir gently rippling the surface of the ocean, and inc gradually, until it often assumes the strength of porary hurricane. Its coming is hailed by the p and literally melting inhabitants, with a deg thankfulness and a sensation of relief, which ca be known by those whose lot it has been to inh oppressive and suffocating atmosphere of these

Were it not for this regular alternation of winds and inland-breezes, the islands of thes would, to Europeans at least, be perfectly unh able. Let such of our readers, therefore, who tiny has never led them beyond the cool sh Britain, conceive, if they can, the sufferings brethren in the tropics, when it happens th "doctor" absents himself for a whole fortnigh time.

In the afternoon, the sea-breeze dies away comes—gradually; after which, for a few hours and sea are again locked in a stillness of rep syncope of motion, which, to a new comer, has thing almost ominous; and as his imagination is rally saturated before his arrival with descript those fearful visitations, the earthquakes—wh there so frequent, though seldom occasioning damage—he instinctively listens, in that period found stillness, for the first rumbling growl pre the volcanic explosion. Earthquakes, however for many years been becoming rarer and rarer West Indies—a fact which seems to confirm the thesis that these islands having, at one time or had their origin in volcanic eruptions, are gra cooling, and that these fearful visitations will so gether cease. There is scarcely a house, howe many years' standing, in the walls of which huge cracks are not to be seen.

The most dreadful scourge of these islands

ious plants of humbler growth, and which love humidity, display their beautiful verdure on their edges. I are sheltered by the wide-spreading branches of mango, mahogany, teak, mimosa, and other woods markable for their stateliness, and clothed in wild and gnificent pomp. The vegetation every where displays that vigorous aspect and brightness of colour so racteristic of the tropics. Here and there, as if for trast, huge masses of trap, blackened by the action the atmosphere, and decayed tremendiæ, present mselves: these blocks, which in colder climates uld be doomed to eternal barrenness, or at most uld only nourish the pale and sickly lichen, here e support to creeping plants of every form and our, which cover with yellow, green, and crimson, sides of the sable rock. In their crevices the succent species are daily renewed, and prepare a soil for ger tenants; from their summits, the old man's rd, and similar weeds, which seem to draw their rishment from the air, hang pendant, floating at the sure of the winds. At a distance is seen the trumpet-, whose leaves seem made of silver plates, as the st reverses them in the beams of the mid-day sun. a solitary spot rises a wild fig-tree, one of the antic productions of the torrid zone. The huge bs of this tree, covered with perpetual verdure, throw en, often from the height of eighty or ninety feet, a ony of suckers of every possible size, from that of k-thread to the vast cable of a ship, without any ible increase in their diameter, and without a joint; se, reaching the ground, become other trees, still maining united. At other times, the suckers, blown ut by the winds, are entangled round the trunk, or e neighbouring rock, which they surround with a work of the firmest texture, as if the hand of man l been employed. Above the rocky summit of the s, the tree ferns, which are the principal ornament our scenery, appear at intervals: convolvuli, and er creeping plants, have climbed their high stems, suspended their painted garlands. The fruits of country, scattered within our reach, and the green es of the bananas and heliconias, planted beneath, ve to minister to our refreshment, and to convey er from the neighbouring spring. On every side, umerable palms of various genera, the cocoa-nut, e, cabbage palm, &c., whose leaves curl like plumes, ot up majestically their bare and even columns ve the wood." Although the foregoing description written for St Vincent alone, the vegetation of se islands is so much alike, that what is said of one apply equally to the rest.

'otatoes are cultivated, but they are watery, and er attain a large size. The yam grown in the ntains, however, is much esteemed; and the seas are well supplied with potatoes from Britain and erica. There are green peas at all seasons, and a t called callaloo, resembling spinach, is much used he interior. The plantain, and what is called the den marrow, are also abundant, and much in rest as food. The flowers indigenous to these islands numerous, and exceedingly rich in colour; and it quently happens that fruits and blossoms are seen wing from the same branch.

Regarding the cultivation of those plants which give West Indies their vast importance, we quote the owing from Loudon's Encyclopædia of Agriculture: he culture of the sugar-cane in Jamaica in some pects resembles that of the hop in this country. ground being cleared, and worked a foot or more depth, the sets or cuttings of the cane, which are tops of the shoots cut off about a foot long, are nted in rows, generally five feet distant, and from to five feet apart in the row, according to the quaof the soil, more plants being allowed for poor than soil. The ground is kept free from weeds, frently stirred, and some earth drawn up to the plants. m each hill, a number of shoots are produced: in months or more, these will generally be from seven en feet high; the skin smooth, dry, and brittle, leaves

with a grey or brown pith and sweet glutinous juice. In this state, the canes are cut, tied in bundles or sheaves, and taken to the mill to be divested of their leaves and decayed parts, and then passed through rollers to express their juice, &c. Cane plantations are formed either in May or June, or in December and January, these being the rainy seasons.

The cotton plant is propagated by seed, which is set in rows, about five feet asunder, at the end of September or beginning of October; at first but slightly covered, but after it is grown up, the root is well moulded. The seed is subject to decay when it is set too deep, especially in wet weather. The ground is hoed frequently, and kept very clean about the young plants, until they rise to a moderate height; otherwise they are apt to be destroyed by caterpillars. It grows from four to six feet high, and produces two crops annually; the first in eight months from the time of sowing the seed, the second within four months after the first; and the produce of each plant is reckoned about one pound weight. When a great part of the pod is expanded, the wool is picked, and afterwards cleared from the seeds by a machine called a gin, composed of two or three smooth wooden rollers of about one inch in diameter, ranged horizontally, close and parallel to each other, in a frame; at each extremity they are toothed or channelled longitudinally, corresponding one with another, and the central roller being moved with a foot-lathe, makes the two others revolve in contrary directions. The cotton is laid upon these rollers whilst they are in motion, and, readily passing between them, drops into a sack beneath, leaving the seeds, which are too large to pass through behind.

Indigo thrives best in a rich free soil and a warm situation frequently refreshed with moisture. Having first chosen a proper piece of ground and cleared it, it is made into little trenches, not above two inches or two inches and a half in depth, nor more than fourteen or fifteen inches asunder. In the bottom of these, at any season of the year, the seeds are strewn pretty thick, and immediately covered. As the plants shoot, they are frequently weeded and kept constantly clean, until they spread sufficiently to cover the ground. Those who cultivate great quantities, only strew the seeds pretty thick in little shallow pits, hoed up irregularly, but generally within four, five, or six inches of one another, and covered as before. The plants grow to full perfection in two or three months, and are observed to answer best when cut in full blossom. They are cut with reaping-hooks a few inches above the root, tied in loads, carried to the works, and laid by strata in the steeper.

In cultivating the coffee, the berries are sown immediately after being gathered, as they are found to retain their vegetative quality only a few weeks. In three months they are fit to transplant, either to a nursery or to a final plantation. In the low lands, they are planted five feet apart, and in the mountains ten feet or more. In three years, the plants will produce a crop, and continue bearing for a number of years. The berries are gathered when they are just about to drop; and are immediately carried to sheds, where they are dried upon cloths, or mats, till the husk shrivels. They are then passed through between wooden rollers turned by a mule, which separates the husk, after which they are winnowed, sifted, cleaned, exposed to the sun for a few days, and then barrelled up for sale."

Various European animals thrive remarkably well in some of the islands. Amongst these may be mentioned the ox, which is much used both for food and labour. Oxen never attain such a size in tropical climes as in this country; and from the labour they have to undergo, the beef is not so good. Horses and mules are abundant in Jamaica, they being principally used for riding or drawing light burdens. Sheep are also plentiful, but the mutton is coarse. Pigs, especially such as are fed upon sugar estates, are very highly esteemed as food; their flesh being described as exceedingly delicate. Goats are kept in considerable numbers for the sake of their milk, which is thought better than cows. Fish are very abundant on the shores of island, and form an important article of cons Their flesh is described, however, as pulpy, an be compared to that of the salmon. The most are those caught in the mountain streams; and land turtle are also frequently met with. Oys to be seen hanging on the pendant branches of low, which grow into the water. The black Jamaica is esteemed as a great delicacy; and what peculiar in its habits. They burrow in during one season, and at others they are fo found far into the interior of the country. It posed that they migrate across the islands w they are found annually. The domestic fowls merous, comprehending almost every kind k this country, except geese and the common d place of these, however, the Muscovy duck, th and the Guinea fowl, thrive remarkably well.

The green turtle is very common in man West India islands, and is much prized as a of food. This species derives its name from being green, and is that most esteemed by There are very few shell-fish in the West Indi are either useful or ornamental. The most are the horned helmet, the strombas gigas, and plecocheilus undulatus, which is confined to St alone.

With such resources, it may be supposed inhabitants live in comfort, from the highes lowest. The mode of life followed in Trinida scribed to us by a resident, is to rise at five, g of coffee, and go to business till seven. Bre then served, and business is suspended for two hours during the heat of the day, during wh the reading-room is much frequented. Wor commences at four or five in the afternoon, and up altogether at nine in the evening.

INSECTS, REPTILES, BIRDS.

One of the most annoying pests of the Wes is the myriads of ants that every where swarm, within as without doors. There are innumerab ties of them—some black, some brown, some la some very small. But, like all the other pro of nature, these little animals, which, by some ficial writers, have been called the "plague of t Indies," prove of the most beneficial consequ the health of the island. They are carnivorou prevent the accumulation of putrid animal Their scent is remarkably acute, and a dead fl or even mosquito, will not lie on the floor for nutes, before a procession of ants will be seen from some distant corner of the apartment, w off the prize bodily to their store-house, to sumed at their leisure.

Perhaps the greatest annoyance experienced settlers in those islands is from the bites of the tos, although these animals are not nearly so dable there, in size or sting, as on the South A continent. In the latter they are so dreadful a that people obliged to sleep out of doors can n protection from the smoke of rank and gree thrown upon a fire to windward of them. islands, however, they are exceedingly troub and a new settler may almost be recognised fr blotched and swelled appearance of his face, ha ankles—in short, every part of his person exp their venomous probosces. They resemble exa British midge, and are in fact of the same fa insects. After a short residence, they cease to annoyance to Europeans, who become callous stings, and whom, indeed, they cease to fix up being some time in the country. They do all trouble the Negroes, whose oily skins are vious to their stings. They are most tormenting the night, and, to guard against their attacks curtains are hung round the bed of every res inhabitant in town or country. The process of

TION OF THE NEGRO POPULATION.—TRADE, &c.

ars to 1834, the British West India Islands were
ated by Negro slaves; but in that year a bill
se Houses of Parliament by which slavery was
l, the planters receiving £20,000,000 sterling
ries of Negro emancipation. This bill declared,
r the 1st of August 1834, all slaves should be-
prenticed labourers; the apprenticeships to
August 1840. In the interval, disturbances
, and much property was damaged, from the
believing that they had now only to work for
es; but in the course of a few months they
to their labour. This they did, however, with
luctance; and in many instances the crops
ined for want of sufficient attendance. The
of the islands in consequence greatly decreased;
it yet reached the amount it stood at before
ng of the Emancipation Act. The Island of
totally abolished slavery in 1834, without re-
the stipulated apprenticeship; and it is highly
g to know, that the amount of crime greatly
d in this island since that period. Bermuda
the example of Antigua, which was imitated
r of the smaller islands, and afterwards by
es. Jamaica and some other islands, however,
till August 1838, when slavery was finally
l in the British West India islands. It was
ed that this event would lead to a considerable
f social disorganisation, but nothing of the kind
; and the conduct of the emancipated Negroes,
y may be termed the *peasantry* of the West
has been peaceful and orderly; and on all oc-
they have manifested a desire to work at fair
nd to improve their moral and intellectual con-
dr Gurney (a member of the Society of Friends),
velled through the West Indies in 1840, and
ished the result of his investigations, corrobo-
official information on this subject, and describes
provement of habits and desires among the pea-
s most remarkable. The only disposition that
rred in the islands, has, it seems, been caused
yers exacting heavy rents for cottages and
-grounds; but this source of disquietude, we
no longer exists, and tranquillity and industry
here prevail.

minica, he found the Negroes manifesting great
for instruction—a thing that cannot be said of
lish peasantry. One day, he observes, "The
athered around us, and a woman came forward
lf of the company, to beg for a school. 'We
gry for a school,' said she; 'we are tired of
for it.' Nor were these idle words; for the
n this and a neighbouring property had agreed
ribe eight dollars per month in part payment
her. Nothing, indeed, can be more eager than
re of the negroes of Dominica for education—
m determined to obtain it; and it is gratifying
that the efforts now making for the purpose
nce considerable and successful. There are
00 scholars in the four Mico schools, which are
ducted, and being quite clear of any peculiar
bias, are acceptable to the whole population."
ms an agreeable piece of information. In Do-
a majority of the lower house in the legislature
sed of coloured persons, and the same class of
are now eligible as jurors, both in this and other
it becomes absolutely necessary that the people
by means of instruction, be prepared for per-
these functions with propriety. Another cir-

cumstance which fell under Mr Gurney's notice at Dominica deserves to be made widely known. During slavery, it was below the dignity of any free person to labour in the fields; and all who could do so preferred to live in idleness rather than work. The abolition of slavery has removed this detestable plea for living in a state of slothful indulgence. *It is now quite respectable to work*—labour in the fields is not discreditable. This indicates an important social improvement. In speaking of Jamaica, Mr Gurney shows, that a coffee estate which he visited is now conducted at a much cheaper rate than during slavery, when the planters were obliged to support not only the actual workers, but all the young, old, sick, and idle. The owner of the estate in question described the two different conditions of affairs as follows:—"One hundred and seventy slaves, or apprentices, used to be supported on this estate. Now, our friend employs fifty-four free labourers, who work for him four days in the week, taking one day for their provision-grounds and another for market. This is all the labour that he requires, in order to keep up his former extent of cultivation. And willingly did he acknowledge the superior advantage which attends the present system. The saving of expense is obvious.

I understood our friend to allow that the average cost of supporting a slave was £5 sterling per annum.

170 slaves, at L.5 per annum, is - - - -	L.850 0 0
Now, he pays 54 free labourers 4s. 6d. per week, one day's labour being set off against rent, for 50 weeks, two weeks being allowed for holidays, - - - - - - -	607 10 0
Saving under freedom, - - -	L.242 10 0"

In the course of another journey, Mr Gurney offers the following useful fact:—"'Do you see that excellent new stone wall round the field below us?' said the young physician to me, as we stood at A B's front door, surveying the delightful scenery. 'That wall could scarcely have been built at all under slavery or the apprenticeship; the necessary labour could not then have been hired at less than £5 currency, or 15 dollars per chain. Under freedom, it cost only from 3½ dollars to 4 dollars per chain—not one-third of the amount. Still more remarkable is the fact, that the whole of it was built under the stimulus of job-work, by an invalid Negro, who during slavery had been given up to total inaction.' This was the substance of our conversation; the information was afterwards fully confirmed by the proprietor. Such was the fresh blood infused into the veins of this decrepid person by the genial hand of freedom, that he had been redeemed from absolute uselessness—had executed a noble work—had greatly improved his master's property—and, finally, had realised for himself a handsome sum of money. This single fact is admirably and undeniably illustrative of the principles of the case, and for that purpose is as good as a thousand." Of the condition of Jamaica generally, Mr Gurney observes—"The imports of the island are rapidly increasing; trade improving; the towns thriving; new villages rising in every direction; property much enhanced in value; well-managed estates, productive and profitable; expenses of management diminished; short methods of labour adopted; provisions cultivated on a larger scale than ever; and the people, wherever they are properly treated, industrious, contented, and gradually accumulating wealth. Above all, education is rapidly spreading; the morals of the community improving; crime in many districts disappearing; and Christianity asserting her sway, with vastly augmented force, over the mass of the population. Cease from all attempts to oppose the current of justice and mercy—remove every obstruction to the fair and full working of freedom—and the bud of Jamaica's prosperity, already fragrant and vigorous, will soon burst into a glorious flower."

Notwithstanding the symptoms of industry and improvement *which prevail*, it happens that the West *Indies suffer from a general* deficiency of labourers, and to relieve this serious difficulty various have been adopted, though without any impor sult. Whether from this deficiency or from th of the seasons, the produce and trade of the islar not kept pace with the improvements in their co dition. We have been unable to find any offici ment which can furnish a view of the export port trade during late years. In 1833, the expo the West Indies amounted to £3,008,248, and they were only £5,410,113. The exports of th nies are considerably greater than their impo consist of four leading articles—sugar, rum, n and coffee. In 1835 they sent out 3,524,209 sugar, 5,453,317 gallons of rum, 507,627 cwts. lasses, and 14,866,580 lbs. of coffee. Much th export from any individual colony was from The imports from the United Kingdom in 1838 a to £3,393,441, a sum so inferior to the valu exports, that there must be a great paymen planters in cash.

The principle on which the trade with the W dies is conducted, like that of all our colonies, cious in the extreme. It consists in our oblig prefer buying from them instead of from Brazi other foreign country, which could supply us at a rate. While we now write, for example, sug be imported into Britain from Brazil at less t the price we are paying for it to the West Indi people of the United Kingdom are in this ma it is calculated, losing several millions per ann clusively of civil and military expenses. It is however, to dilate on this absurd system of tra present certain plans are in contemplation for the tariff of import duties, which leads to such injury to the mother country, and which is comp by no commercial advantage whatsoever.

The currency employed in the West Indi imaginary money, and has a different value in colonies. The following are the values of £1 ling, and of a dollar, in the currencies of the islands:—

	Sterling.	Currency.	Dollar.
Jamaica, - - - -	£100 =	£140	1 =
Barbadoes, - - - -	100 =	133	1 =
Windward Islands (except Barbadoes), - - -	100 =	175	1 =
Leeward Islands, - -	100 =	200	1 =

As far as we know, there is not any censu population of the West Indies later than that The following is the census for that year: the of the population in Jamaica, however, is only proximation, there being no available census island:—

Colonies.	Whites.	Free Coloured.	Apprenticed Labourers.
Antigua, -	1,000	33,432	...
Barbadoes, -	14,959	5,146	82,807
Dominica, -	840	3,606	14,384
Grenada, -	891	3,786	23,536
Jamaica, -	36,000	...	...
Montserrat, -	330	974	6,355
Nevis, -	700	2,000	8,722

EAST INDIES.

the fairest and richest portion of India. This
t, in its largest extent, may be described as a
ircle, with its base extended along the line of the
leh Mountains, and its curve running along from
ana on the Indus, to Delhi, Gualior, Punnah,
hulpoor, and Balasore, where it meets the sea
e mouths of the Ganges, thence along the coast
ittagong, and north by Silhet and Rungpore, to
e the country of the Brahmaputra.
first sight of India to European voyagers has
which can please or interest. The coasts are
kably flat, and frequently dangerous to approach
gh the raging surf; the shore is only discernible
tall cocoa-trees which surround the villages or
es. This extreme flatness of the shores of India is
the peculiar distinguishing traits of the country,
exceedingly disadvantageous in a maritime com-
al point of view.
southern district of this magnificent valley is
Bengal, and extends along the sea from Chitta-
o Balasore, about four hundred miles, and reaches
the same distance northward. The sea-coast is
e most fertile or useful part of this territory;
part of it towards the centre being composed of
y ground, or of mud islands, among which the
ies of the river are spread like net-work. These
s are covered with a rank vegetation of reeds,
are sometimes twenty or thirty feet high; or
rees and underwood so tall and dense, that it is
sible to penetrate them. They afford shelter to
and other wild animals, but the air of the whole
n is pernicious to health. About 150 miles up-
, the soil becomes higher and less marshy, so as
rd good ground for cultivation; and the country
fertile and thickly peopled. It is in this district,
diately above the mouths of the Ganges, that
ta, the capital of British India, is situated. The
ations of the Ganges cover and fertilise immense
of the level country near the river, while others
remote procure the same advantages from an
ial irrigation. Luxuriant fields, divided by groves
l trees, with villages under their shelter, and
ing with a population beyond any thing that
e can show, form the general features of the vast
l plain of Bengal.

DIVISIONS OF THE COUNTRY.

modern territorial and political subdivisions of
may thus be specified:—First, Northern Hin-
, an extensive and rugged territory, comprehend-

country between the
leja and Jumna.
rwal or Serinagur.
rces of the Ganges.
, Hindostan Proper,

4. Kemaoon.
5. Palnkhandi.
6. Bhotant.
7. Dominions of Nepaul.

which is the most com-

prehensive division. It stretches across the centre of India, and obtains the most prominent place in the history of the old Mahommedan empires of India. It reaches south to the Nerbudda river, where the Deccan commences, and includes the following thirteen large provinces:—

1. Bengal.
2. Bahar.
3. Allahabad.
4. Oude.
5. Agra.
6. Delhi.
7. Lahore.
8. Cashmere.
9. Ajmeer.
10. Mooltan.
11. Cutch.
12. Guzerat.
13. Malwa.

Third, The Deccan.—This division lies next, in a southerly direction, to the above, extending from the Nerbudda river on the north, which flows into the sea on the west coast, to the Krishna, a river flowing into the sea or Bay of Bengal on the east coast. Between these rivers lies the Deccan, a much less fertile division of India than the preceding; Bombay, a small island on the west coast, belongs to the province of Aurungabad in this division. The Deccan comprehends the following provinces, a portion of which once formed the Mahratta empire:—

1. Gundwana.
2. Orissa.
3. The Northern Circars.
4. Candeish.
5. Berar.
6. Beeder.
7. Hyderabad.
8. Aurungabad.
9. Bejapoor.

Fourth, India South of the Krishna.—This division forms the extreme southerly portion of the Indian peninsula, and comprehends the following provinces:—

1. Canara.
2. Malabar.
3. Cochin.
4. Travancore.
5. Balaghaut, ceded districts.
6. Mysore.
7. Coimbatoor.
8. Salem, and the Barramahal.
9. The Carnatic, in which is situated Madras.

Besides the foregoing divisions and provinces, the large territories of Ava and the Burmese empire, lying east from the Brahmaputra, are now attached to India, besides other conterminous regions in different quarters.

HISTORY.

What was the original political condition of the vast territory now composing the British Indian empire, it would be needless to detail minutely. Like other portions of Asia, it was early inhabited by a primitive people, more or less barbarous, professing different pagan religions, and speaking many more different languages. The principal religion, however, was Hindooism, which we shall afterwards allude to; and it has been said by some historians that the early Hindoo race of inhabitants manifested many symptoms of civilisation, and even a knowledge of some of the sciences. However this may have been, the inhabitants generally were in some measure an industrious but simple race, and little inclined to war. Reasoning from what has occurred in their history, as well as from the information communicated regarding them, they seem, from the earliest times, to have had little or no care with regard to who ruled over them, provided they were ensured in the possession of their ancient religious usages, and their system of living in small communities, under a primitive species of local government. They were reckless of what sovereign was placed over them, or to what dynasty they were transferred, so long as the internal economy of their village districts remained the same. This species of political apathy produced the results which might have been expected. From the most remote period of which any record is preserved, the inhabitants of India, including those tribes which possessed more decided warlike propensities, or who had the spirit to resist aggression, were subjected to the government of strangers, who seized upon their territories, and made them the objects of taxation. Among other warlike princes who thus made inroads on the country, Alexander the Great, in the course of his ambitious career, marched with an army to India, the northern part of which he conquered.

Of this remote period of Indian history, little is correctly known; all that may be said of it is, that the Greeks and Romans were supplied with their articles of luxury from Hindostan, and many centuries this eastern clime was supposed ill-instructed inhabitants of distant parts of Europe, to be the richest and most sumptuous on the globe. The tales related of Indian appear to have in time excited the avarice tion of Mahommedan or Saracen chiefs. This barbarous though intrepid race, who made successful inroad upon India, was Mahmoud, Ghizni, or Affghanistan, a kingdom on the north India. Mahmoud commenced his successful tions into India about the year 1000, and he them till 1024, making the destruction of pagan more the object of his visits than the acquisition wealth or power. In this period of twenty-five he had subdued a considerable number of princes, and, notwithstanding his professions immense tributes in gold and every kind of commodity. A successor of Mahmoud, named med, after carrying on war with the Indian some time, at length, about the year 1193, Hindostan with an exceedingly large force, down all opposition. The king of Delhi was battle, and having advanced to that ancient Mahommed there left a viceroy to maintain rity. In this manner a Mahommedan dom for the first time established in the heart of in one of its greatest cities; and thus commenced Affghan or Patan sovereigns and their dynasty.

The dynasty so planted continued in existence rather more than three hundred years, when or 1526, it was subverted by Baber, who was one of the most adventurous warriors of his who, like his prototype Mahommed, was of the faith. Baber was either descended from a Tartar chief, or in some way, not clearly explained historians, connected with a race called Mogul assisted him in his attempts upon India; causes of this nature, the empire which he founded Hindostan has ever since been called the Mogul From the year 1526, a series of Mahommedan rors, whose seat of authority was at Delhi, largest and finest portions of India. By country was in many places newly subdivided vinces, and put under the government of tributary or nabobs, who superseded the Hindoo rajahs princes. One of the greatest of these Mogul was Akbar, who flourished between the years 1605. By his daring and judicious manager central provinces were preserved in complete lity, and Guzerat, Bengal, and part of the Deccan added to his already extensive empire.

While the emperors of India were thus est their power, multifarious schemes were formed Europe for getting possession of some of the not some portions of the territory, of Hindostan commodities of Indian manufacture or produce hitherto imported into the European states means of tedious overland journeys, or part Red Sea, and were endangered in their passage attacks of ferocious Tartar and Turkish tribes discovery of a new and safe road to India thus a matter of very great consequence. A route round the Cape of Good Hope was at last found Portuguese, who, under the command of Gama, in 1498, landed in Hindostan, on the Malabar, where they at once established the The whole commerce of the East Indies was in hands of the Portuguese for nearly a century—was the golden age of Portugal. Lisbon became great depôt of Indian spices and other commodities greatly to the envy of the Dutch and other Portugal was united to Spain in 1580—the Spanish oppressed Holland, and caused it to revolt—this was followed by the capture of the Dutch ships to Lisbon—and this capture compelled the

ple of one by taking part against another, and end getting the advantage of both. Besides, it t for some time that the British disclosed any on of securing the jurisdiction of provinces, or erty in the soil. A watchful hypocrisy led them d, on all occasions, a reverence towards the poli- way of the native emperors, rajahs, and nabobs. riginal East India Company, with its charters erent times disputed and renewed, continued hout the seventeenth century to carry on a pro- traffic with the East. Its factories were ex- to Java, Sumatra, Borneo, the Banda Islands, s, Malacca, Siam, the coasts of Malabar and andel. In 1640, the native authorities gave per- n for the building of Fort St George, at Madras; 1645, a factory was established on the banks of ughley, a branch of the Ganges near its mouth, formed the foundation of Calcutta. The island mbay was also procured as a settlement in 1654-5, a struggle with its Portuguese possessors. The of the Company were not, however, in a prospe- ate; and soon after the Revolution of 1688, the n of the validity of the old royal charter was . The consequence followed of the Company ing able to perform its obligations, an amount es occasioned by wars, infidelity of officers, ex- ance, &c.; and Parliament, in 1693, granted a r to a new East India Company, on condition of of £2,000,000 sterling to the state, and which quired to carry on King William's wars. But at contentions between the two Companies soon it necessary to unite them, and a union was d in 1702, when an act of Parliament was passed, shing the conjoined association under the title of ited Company of Merchants trading to the East Stock was raised by the sale of shares, and the olders to a certain amount were entitled to elect ectors of the Company.

progress of the Company's settlements in India several occasions about this period, caused by perior skill of the British in medicine. In 1715, assy being sent on a commercial commission to it happened that a medical gentleman named on, who accompanied the factors, had the good to cure the Emperor Feroksere of a severe ill- which could not be overcome by the ignorant physicians. In gratitude for this important ser- hough it is likely some very valuable presents e Company had an equally liberalising effect, the r granted liberty to the Company to purchase in thirty-seven townships in addition to that of a; he also conferred upon them some important rcial privileges, which soon rendered Calcutta a ing settlement.

charter of the East India Company was from time renewed during the eighteenth century, (but not without great difficulty) against a ul opposition. But loans to government carried lways through these embarrassments. In 1744, dvanced £1,000,000 at three per cent., in con- ion of an extension of their privileges till 1780. to we have seen this company of English mer- acting only for the avowed object of commer- ercourse with India; we now open a new page r history, and show the origin of their political

East India Company assumed the qualifications litary and political power in the year 1748. But dvances towards territorial dominion were re- by a rival, which gave them no small trouble. ompetitor was France, which had in the mean astened to share in the commerce and spoils of In 1746, a French battalion had destroyed the f the nabob of the Carnatic, and soon after the officers succeeded in disciplining Indian troops ng to the European method. The inferiority native Indian troops opposed to European sol- and the facility of instructing Indian soldiers, by the name of Sepoys, in the European tactics,

was thus proved. Ambition and avarice, political and mercantile cunning, could now act on a larger scale; and the independence of the Indian princes was gone whenever this trading Company, which was already encroaching upon all the rights, both of the rulers and the people of these countries, should establish a permanent military force. Thus far the military organisation of the Company had been merely on the defensive; it now became able to act offensively; and the entire difference of the European and Indian notions of law could never fail to furnish opportunities to put this new means of power into action. The rights of succession, and all the rights of princes, subjects, and families, were so much disputed on the different principles of the Indian, Mahommedan, and British laws, that the Company, which often interfered as arbitrator, easily succeeded in extending their legal jurisdiction. If called to account in England for any of its undertakings, it was easy to uphold the correctness of its conduct, politically, on the ground of self-defence, which at the distance of several thousand miles, could not be called in question; and, in legal matters, by taking advantage of the impenetrable labyrinth of the law. Edmund Burke, who experienced, in the case of Warren Hastings, the head of the Company's affairs in the east, this impregnability of the association, accused them justly "of having sold every monarch, prince, and state in India, broken every contract, and ruined every state who had trusted them." In 1749, the robberies of the Company began with the protection of the pretender of Tanjore, a fine province of the Carnatic. Under pretence of illegitimacy, the nabob of this district was driven out for the purpose of obtaining some cessions of territory, and then restored on making further concessions. The rapid progress of the Company in the art of extending their possessions, appears from their treaties with Surajee-Dowlah, the nabob of Bengal, whom they contrived to depose in 1757, when large and rich provinces were the reward of their faithless policy. The French, who in a similar manner had acquired considerable territorial possessions in the Carnatic, now came into collision with the British merchants, and a hot war was carried on in India between these contending Europeans. The indecency of this conflict as to which party should be the greatest robber, seems to have shamed both France and England, and commissioners were mutually sent to India to reconcile the differences which existed, as well as to check the acquisition of territory either by the English or French companies. As a matter of course, this affectation of justice ended in nothing. After the commissioners had agreed that each should restore its acquired territories, and after a "solemn" treaty to that effect had been arranged, hostilities commenced as before. It would be needless to recount the particulars of this struggle for power; it will suffice to state, that the French ultimately were deprived by the British of their possessions.

By the defeat of the French forces in 1761, the British were left at liberty to pursue their schemes on India, being in no small degree favoured by the unhappy political condition of the Mogul empire. This large empire came under the rule of Aurungzebe, a descendant of Akbar, in 1658, and his reign lasted till his death in 1707. Under this celebrated Mahommedan emperor, the empire of the Moguls came to the height of its glory, and attained its largest extent. After Aurungzebe had added to it the kingdoms of the Deccan, it included nearly the whole peninsula of Hindostan, with the neighbouring regions of Cabul and Assam. The revenues extorted from this populous and wealthy territory amounted to £32,000,000 sterling. During the reign of Aurungzebe, it was attacked by the Persians under the bold prince Nadir, and also by a growing nation, called Mahrattas, whose kingdom comprehended large portions of the provinces of Malwa, Candeish, Aurungabad, and Bejapore, in the Deccan. By Nadir, and his successor Ahmed Abdallah, the Mogul empire, after the death of Aurungzebe, was almost entirely subverted to the character of a tributary to the Persians. Under these circumstances there was scarcely a power that did not consider itself entitled to tra the feeble authority of the throne of the Mogu between the Affghans, whose kingdom lay to the west, and the Mahrattas, the empire was distract made the object of greedy contest. The Affgha at length victorious over their enemy; and in 17 placed a descendant of the old dynasty on the and in the possession of the empty but still ve title of Great Mogul, to be the tool or captive first daring power which should seize the capit

From this period the dignity of the empire w end, and a favourable opportunity was offered various dependent princes to throw off their all as well as to enterprising chiefs to take adva the unsettled state of things, and establish ne doms for themselves. In this state of general tion, a bold Mahommedan adventurer arose obscure rank, named Hyder Ali, who, by sum round him bold and predatory bands, and wag with considerable address, established his pow sovereign in the Mysore, a territory forming on most remarkable of those elevated table-lan diversify the southern provinces. Hyder was su in 1782 by his son Tippoo, a person equally bold less prudent and fortunate. Against both these rulers the British for a number of years waged various success. In 1792, Seringapatam, the c the Mysore, was besieged by the Marquis Co with a strong British army, and after some sh sistance, Tippoo was fain to offer terms of su He agreed to give up half of his dominions, £3,500,000 in bullion. For the fulfilment of th he was under the necessity of giving up two of as hostages. Having fulfilled his engagemen young princes were returned in 1794: but afte again commenced hostilities, and in 1799 the forces, under General Baird, once more attac now captured Seringapatam. In the general s which occurred in entering this strongly fortifi Tippoo was shot, and his body was afterward among a heap of the slain. Thus terminated a which, though short, and limited in respect of rial dominion, was undoubtedly the most vigo best organised of any that had sprung out of th of the Mogul empire. The principal war in w East India Company was engaged after this st contest, was that with the Pindarees, roving Mahrattas, who, without any territory, carried datory warfare against all whom they could impunity. The war with the Pindarees was great difficulty, and it cost the British a nu years before they finally quelled them. The l war terminated in 1817, and it was followed b test betwixt the British and the Birman empir was successfully closed in 1826, and by which t pany gained a considerable territory along th Bengal, east of the Brahmaputra river. By g going, and other less conspicuous contests wit princes, among which may be reckoned the wa the Nepaul, in 1814, and also by means of pe negotiations, and voluntary or involuntary resi territory, including the capture or cession by the French and Dutch settlements, the Britis was at length established as supreme over ne whole of India.

EXTENT AND POPULATION OF INDIA.

The following has been given by the best au as an estimate of the extent and population of ritories now included in British India:—

	Square Miles.	P
Presidency of Bengal, -	220,312	6
Madras, - - - - -	141,923½	1
Bombay, - - - - -	59,438½	
Districts, the population of which is doubtful,	91,250	
	512,923½	

lo another statement, the territorial extent are miles, and the population is 89,577,206. of the allied or protected, that is, the sub- estimated at 614,610 square miles; their wever, is not supposed nearly equal to that ries under the immediate government of Mr Hamilton, in the second edition of a Gazetteer, estimates it as follows:—

am, - - - -	10,000,000
poor Rajah, - -	3,000,000
g of Oude, - - -	3,000,000
kwar, - - -	2,000,000
ra Rajah, - - -	1,500,000
ore Rajah, - -	3,000,000
re and Cochin, - -	1,000,000
loondee, and Bopaul, -	1,500,000
and other petty states,	15,000,000
	40,000,000

author makes the following conjecture as that still remain independent:—

- - - - -	4,000,000
Rajah Runjeit Singh, -	3,000,000

- - - - -	2,000,000
e and other districts belong-	
the King of Cabul, -	1,000,000
	11,000,000

give for the whole of India a population f 140 millions; but in the foregoing esti- is not taken of the portion of India beyond including part of the Burmese territory, ding to Mr Hamilton, an extent of 77,000 and a population of 301,000.

he Company have governed their Indian r means of the presidencies of Calcutta, Bombay, each of these places being the s of a local military and civil government. re will be another presidency, that of Agra, te in the interior. The whole are under control of a governor-general appointed h court; these governors-general seldom situations above a few years. Mr Pitt, in an act establishing a Board of Control, six privy-councillors, to superintend the ncerns of the Company, which check is d, and reappointed under the act of 1833. assession of so large a territory as India, require to keep up a numerous and well- med force, which is composed chiefly of poys, with British officers, and partly of in Great Britain. The Company further ber of queen's regiments, who have double them. Mr Hamilton gives the following the amount of the forces employed:—

illery, - - -	15,782
ive cavalry, - -	26,094
— infantry, - -	234,412
gineers, - - - -	4,575
en's troops, - -	21,934
Total, - -	302,797

irregulars of all descriptions amounted to

This formidable army of native and ldiers is distributed throughout Hindos- nted stations, forming a chain of military eeping up a continual communication with the various presidencies. Latterly, the roops may be different from that above 830, they amounted to 224,444 men.

ons which subsist betwixt the Company utary and dependent states may thus be The Company undertake the defence of it prince's territories against all enemies, foreign. He is bound, on the other hand, to enter into no alliances with other sovereigns or states without the Company's consent; and he pays them a certain annual subsidy out of his revenues for their protection, while he generally keeps up an army at the same time, for the maintenance of internal tranquillity. In some cases, instead of paying a subsidy, the prince cedes a portion of his territories, of which the Company draw the entire taxes. The Company keep a resident at the prince's court, who is entitled to demand an audience at any time; and by this agent, the Company do in fact interfere pretty regularly in the internal concerns of the state, particularly in settling the succession to the throne. The princes are in reality mere viceroys, or rather tax-collectors for the Company; and when in any state gross mismanagement or breach of engagement repeatedly occurs, these pageants are dethroned and pensioned off, and the Company take the government of the country into their own hands. The Company's protection is often found to shelter internal misgovernment; for the prince, being secured by the British army against the resentment of his own subjects, is tempted to indulge the more freely in extortion and oppression.

REVENUE SYSTEM OF INDIA.

To sustain not only the above military force, but the civil management of India, a revenue of £22,000,000 requires to be levied. About two-thirds of this large sum is derived from a tax on land; and as the mode of collecting, imposing, and administering it, enters deeply into the system of Indian policy, and has a powerful influence on the social condition of the people, we shall here attempt its explanation.

Under the old Mogul empire, the sovereign was considered the universal proprietor of the soil; but the ryots, or cultivators, or actual owners, were held to have a perpetual right of occupancy, so long as they paid the fixed annual tribute or rent demanded by the sovereign. The rent was fixed at a third, and sometimes at a half, of the value of the produce, and the functionaries appointed to ascertain the amount leviable, and to collect it, were called *zemindars*. In 1793, Lord Cornwallis, governor-general, with a view to establish a better system for all parties, changed the zemindars from the character of hereditary tax-collectors to that of proprietors of the soil, though still accountable to government for the rent. This created a vast deal of misery at the time; thousands of poor ryots were ejected from their ancient possessions; but ultimately the country at large was benefited. It was arranged that the sum payable by the ryot for several years, should be fixed as the permanent rent; one-tenth of this was allowed as the zemindar's share, and the other nine-tenths the proportion payable to the government or Company. The rent paid to the Company being fixed, great quantities of land which had been "concealed," that is, left out of the rough and partial returns formerly made, and which had lain in a wild state, or in pasture, were now put under crop. The practice is, to allow the ryot to occupy waste lands rent-free for three years, and to charge only a moderate rent for a few years more. In this way a considerable extension of cultivation has taken place; and some of the zemindars have acquired wealth. From their improvident habits, however, such wealth seldom lasts more than one generation; and no progress has been made towards the institution of a rural aristocracy. The Company have begun very recently to retrace their steps. When zemindaries fall into their hands, as they are always doing from time to time, by the inability of the holders to fulfil their engagements, the Company replace the ryots as nearly as they are able in their original situation, allowing them to hold their lands under payment of a rent which remains fixed, either permanently or for a period of years. The Company in this case come in the room of the zemindar, and collect the rents in detail from the ryots by their agents.

This system of "zemindary settlement" prevails generally in Bengal, Bahar, Orissa, and Benares. It

has also been tried on a small scale in the Madras presidency, but with very bad success; but in a modified form it has long existed in some parts of Southern India, where hereditary chiefs, called *polygars*, occupy a similar situation to that of the zemindars in Bengal.

There are other two modes of collecting the rent or land-tax (for it may receive either name); the *Ryotwar*, and the *Mouzawar*.

The ryotwar was first extensively introduced by the late excellent Sir Thomas Munro, when governor of Madras, in 1802. In this system, the government collects the rent directly from the ryots, without the intervention of zemindars. An actual survey was made, with great labour and expense, of the lands of the villages, in which it was attempted to fix the extent and value not merely of every occupancy, but of every field. The records showed the whole sum which the village had paid in former years; and from this, with the opinions of practised assessors, checked and guided by the advice of the village *potail* and *curnum* (the headsman and accountant), an estimate was formed of the gross produce, forty-five per cent. of which was assumed as the rent. The sum thus ascertained was fixed as the maximum which the tenant should be called on to pay. The rent is taken from the ryots in monthly payments, and very summary means are used to extort it. The system was extremely unpopular at its introduction, and occasioned great distress; but this was attributed to the excessive amount of the tax, rather than to defects in its imposition. The reader should be told, that the perquisites of the potail, curnum, brahmin, astrologer, schoolmaster, and a long train of other village functionaries, are supposed to absorb ten per cent. of the ryot's crop, so that the forty-five per cent. which government took in a good year, was, and was meant to be, one-half of the clear produce after this deduction was made. In consequence of the outcry against the tax, considerable abatements were made; and the ryotwar system remains in operation in a part of Madras presidency at this time, with, we believe, comparatively few complaints.

Village settlements.—The third system is the *Mouzawar*, or "village settlement." A village in India does not mean a collection of houses at a particular spot, but corresponds to what is called a township in America. "It is a tract of country (says Mr Hamilton) comprising some thousands of acres of arable and waste land; politically viewed, it resembles a corporation or township. Its proper establishment of officers and servants consists of the following descriptions:—The potail, or head inhabitant, who has the general superintendence of the affairs of the village, settles the disputes of the inhabitants, attends to the police, and performs the important duty of collecting the revenues within his village—a duty which his personal influence, and minute acquaintance with the situation and concerns of the people, render him best qualified to discharge: the curnum, who keeps the accounts of cultivation, and registers every thing connected with it: the *talliar* (constable), or *totie* (watchman); the duty of the former appearing to consist in gaining information of crimes and offences, and in escorting and protecting persons travelling from one village to another; the province of the latter appearing to be more immediately confined to the village, consisting, among other duties, in guarding the crops, and assisting in measuring them: the boundary man, who preserves the limits of the village, or gives evidence concerning them in cases of dispute: the superintendant of the tanks and water-courses, who distributes the water therefrom for the purposes of agriculture: the brahmin, who performs the village worship: the schoolmaster, who is seen teaching the children in the villages to read and write in the sand: the calendar brahmin, or astrologer, who proclaims the lucky or unpropitious periods for sowing and thrashing: the smith and carpenter, who manufacture the implements of agriculture, and build the dwelling of the ryot: the potman, or potter: the fisherman; the barber; the cowkeeper, who looks after the cattle; the doctor; the dancing girl, who att rejoicings; the musician, and the poet. These and servants generally constitute the establish a village; but in some parts of the country it i extent, some of the duties and functions above d being united in the same person; in others, it the number of individuals which have been de Under this simple form of municipal governm inhabitants of the country have lived from tim morial. The boundaries of the villages have b seldom altered; and though the villages themsel been sometimes injured, and even desolated, famine, or disease, the same name, the same lim even the same families, have continued for age inhabitants give themselves no trouble about th ing up and division of kingdoms; while the remains entire, they care not to what power it i ferred, or to what sovereign it devolves; its economy remains unchanged; the potail is head inhabitant, and still acts as the petty ju magistrate, and collector or renter of the villag

It will be understood that under the zemind tlement, the government transacts with one in for an extensive district, probably as large as a under the mouzawar or village settlement, it t with the chief person of the village for the wh munity; and, under the ryotwar settlement, i acts with each individual cultivator. It may b to add, that in India a ryot seldom holds m than he and his family are able to cultivate, a there are few farm-servants in our sense of the

Of the three modes of settlement, it may b that the zemindary plan has yielded the largest r the method of "village settlement" does no much more trouble to the government, and i liked by the cultivators; the ryotwar is the n pensive and troublesome, and has been the le ductive of revenue; but it would be the most e and most advantageous to the people, if the justice were not defeated by the frauds of th officers intrusted with its details, and whose co is almost universal.

The revenue derivable from land by these processes of exaction, amounts, as has been two-thirds of the whole revenue of the Company sum of £14,000,000. The next greatest head nue is the receipt from native princes, or fro and conquered countries, and which averages in from £7,000,000 to £8,000,000.

The Company have hitherto gained a million per annum by the monopoly of opium. Th offered a price annually, which has been fixe lowest rate that will remunerate the produc ryots, whose lands have been suited to the cul entered into engagements to deliver certain qu About two-thirds of the opium used to be smug China, until the Chinese stopped the importati one-third was sent to the eastern isles, Java, S &c. Salt has also been an article of valuable taxa has been manufactured on the coast of the Bay o exclusively for the Company. Before it rea consumer, its price is enhanced five, eight, or The Company have realised a gross revenu millions per annum from this monopoly.

The customs drawn by the Company consis of taxes collected at the seaports on foreig brought in, and partly of *transit* duties levied passing through the country. There are p duties paid in passing from one presidency to town duties on certain articles at the gates o and market duties levied at the market statio fairs are held. To collect these taxes, and guar contraband trade, there are customhouses, cal *kies*, at every considerable village. In the singl of Madura, with a million of souls, in Madra dency, there are twenty-one customhouses, which has four or five subordinate establishme at these stations, even when no duties are exig are charged by the native officers for the tr

amination, and a good deal of delay is caused in the ansmission of merchandise. These taxes are sources ' annoyance and occasional extortion to the trading asses. They produce a gross sum of £1,800,000, hich is reduced to £1,600,000 by the charges of col-ction, &c. We believe that a considerable portion of ie revenue derived from these duties on traffic is laid it by the Company in the construction of roads and ridges, where improvements of this kind are most anted.

Total revenues,	£22,054,416

In 1833–4, the annual revenue was £13,680,165, but iis large sum scarcely covered the expenditure, in-uding interest on the debt due by the Company, which t that time amounted to £35,463,483. As India, by ie taxes which it contributes to the Company, clears ie cost of its own protection and all its other expenses, may be considered as the only foreign possession of ritain whose connexion is not a cause of loss to the other country. By means of its vast import trade, idia forms one of the best customers for British anufactures, and is therefore a source of wealth to ie United Kingdom. In this respect, India has been lled "the right arm of England."

As may be generally known, an act of Parliament as passed in the year 1813, permitting the free trad-g of British subjects with India, reserving the com-erce of China to the Company; the territorial and mmercial branches were separated, as well as all ccounts connected with them; and the king was em-owered to create a bishop of India, and three arch-eacons, to be paid by the Company. This act, which as in force till the 22d day of April 1834, did not afford rfect freedom of trade to India, yet it led towards at desirable result, and greatly increased the com-erce with the East. By the act 3d and 4th Will. IV. ap. 85, passed in August 1833, entitled "An act for fecting an arrangement with the East India Company, id for the better government of his Majesty's Indian rritories, till the 30th day of April 1854," the com-any were deprived of the exclusive right of trading ith China, and ordained to close the whole of their mmercial business, and make sale of their merchan-ise, stores, and effects, so far as regarded commercial sets. It was further ordained, that the whole debts f the Company should be chargeable upon the revenues ' their Indian territories, but leaving a yearly divi-nd of ten per cent. to be retained by the Company; is dividend to be redeemable by Parliament. The ompany to pay into the Bank of England two millions nnually, till the sum of twelve millions is accumulated, s a security fund to the government. The other prin-pal provisions were—A board of commissioners, to be ppointed by the king, to superintend affairs of India; engal presidency to be divided into two presidencies -Fort William (Calcutta) and Agra; the whole govern-ent, civil and military, of India, to be vested in a vernor-general and councillors.

The 81st clause is in these terms:—"And be it enacted, That it shall be lawful for any natural born subject of his majesty to proceed by sea to any port or place having a customhouse establishment within the said territories, and to reside thereat, or to proceed to and reside in, or pass through, any part of such of the said territories as were under the government of the said Company on the 1st day of January 1800, and in any part of the countries ceded by the nabob of the Carnatic, of the province of Cattack, and of the settlements of Singapore and Malacca, without any license whatever; provided that all subjects of his majesty, not natives of the said territories, shall, on their arrival in any port of the said territories, from any port or place not within the said territories, make known in writing their names, places of destination, and objects of pursuit in India, to the chief officer of the customs, or other officer authorised for that purpose, at such port or place as aforesaid." Clause 86 permits his majesty's natural born subjects to purchase lands in India: 87 enacts that no native of India, or natural born subject of his majesty, shall, by reason only of his religion, place of birth, descent, colour, be disabled from holding any place, office, or employment under the Company: 112 enacts that St Helena be placed under his majesty's government.

By this act, it will be perceived that several very important provisions are made for the benefit both of Hindostan and Great Britain. India is henceforth open to the settlement of British emigrants; trade may be carried on freely with either India or China; and Indo-Britons, Hindoos, or other natives, are now placed on a level as to political, military, or civil distinctions, with Englishmen. It is stipulated that the governor-general in council is empowered to legislate for India, and for all persons, whether British or native, foreigners or others: if the laws thus made by the governor-general are disallowed by the authorities in England, they shall be annulled by the governor-general. In virtue of these arrangements, it is evident that India, with all its social improvements, retains very much of the character of a despotically governed country; no part of the population having any right to interfere in the legislation or executive. To enlightened foreigners this may prove an inconvenience; but, in the extraordinary condition of the whole Indian territory, a more liberal policy would most likely be unsuitable if not injurious. As it is, England may expect to derive very great advantages from the policy pursued. To use the words of Dr Wallich, superintendant of the Company's botanic gardens at Calcutta—"The Company's territories in India are productive of every article which can conduce to the happiness of men; and it only requires skill, and ingenuity, and encouragement, both to the natives and Europeans in India, to select every thing that can possibly be desired." As the Indian population possess a taste for British manufactures, a reciprocal benefit will be the result of every increase of intercourse.

NATIVE POPULATION—HINDOOS.

The bulk of the population of India is composed of Hindoos, the primitive inhabitants of the country, and forming one of the most ancient nations in the world. This race was distinguished for their humanity, gentleness, industry, and were polished by letters and arts, at a time when most of their Asiatic neighbours were yet only in the first stages of civilisation. This remarkable people have preserved their national character for thousands of years, even under the dominion of foreigners, and have retained to the present day their language, their written characters, their local government, religion, manners, customs, and habits of life. The Hindoos are in general of a brownish-yellow complexion, but the higher and richer classes are almost as white as Europeans. They are somewhat above the middle height, well proportioned, and very flexible and dexterous. Temperance, frugality, hospitality, and obliging manners, are the favourable traits in their character; but they are now reproached with indolence

and avarice. With proper discipline, they form excellent soldiers and faithful servants of the Company. They possess great natural talents, but are at present deprived of opportunities for their developement. They practise agriculture, breeding of cattle, fishing, hunting, and mining, and are largely engaged in manufactures, commerce, and navigation. They manufacture cloths of great variety and value, particularly cotton and silk, among which are the finest muslins and shawls, mats, cordovan leather, &c., and are inimitable in dyeing. In the arts of music and singing they are backward, but in dancing, statuary, and architecture, they are more advanced. They are acquainted with arithmetic, astronomy, and chronology, and are fond of poetry.

The most extraordinary peculiarity in the Hindoos is their division into *castes*, or perfectly distinct orders of society, which have existed from the remotest times. There are four castes, and it is strictly enjoined by the Hindoo religion that no transition from one to another shall take place; no connexion between them by marriage or any other way is allowed, and no individual of one class can assume the habits or engage in the occupations of another. The distinction is complete in every sense, hereditary and personal; all the privileges or disabilities are inherited; no one is permitted to become what he is destined to be by his natural abilities, but is obliged to become only what his birth permits, or to remain what it condemns him to be. The slightest transgression of these laws is punished with loss of caste, and sometimes, in particular cases, with death. Even the difference of food is precisely marked out. The three higher castes are prohibited entirely the use of flesh; the fourth is allowed all kinds except beef; all others are outcasts, and may eat what they please. Thus, the lower the rank of the Hindoo, the less he is restricted in his meat and drink; but, on the other hand, the burdensome restrictions increase with the inferiority of rank.

The first, or most noble caste of the Hindoos, are denominated Brahmins; they are priests, scholars, teachers, lawyers, and state officers, and are required to be virtuous, learned, peaceable, just, and self-denying. The second order is the Kyetra, who are kings and warriors; and they are required to have a thirst for glory, to die rather than retreat, and to be generous to captives. They preserve the ancient name of rajaputs, by way of distinction, in their old hereditary dominions. The third order, which is called Bhysya, or Vaisa, are husbandmen and merchants. The fourth caste is that of the Soodras, who are labourers, and they are enjoined to serve with patience and fidelity. A lower caste, if it can be called such, are the Parias—those unhappy beings who have lost their station in the noble orders, and who are obliged to do whatever no one else can do without pollution. They are not only reckoned unclean themselves, but they render unclean every thing they touch. They are deprived of all civil privileges, and stigmatised by particular laws, regulating their mode of life, their houses, and their furniture; they are not allowed to enter the temples of the other orders, but must worship by themselves. Their houses are miserable hovels, distant from cities and villages.

The Brahmins, who are not legitimately entitled to possess property, and who must live upon the bounty of others for their support, cherish in the people the most debasing superstitions, and exact from them the most profound veneration. Instead of being holy, harmless, and undefiled, they are vicious, tyrannical, avaricious, and to the last degree impure. This infamous aristocracy is the curse of India, and presents a barrier to the attempts which have been made to meliorate the condition of the inferior orders. We believe the Kyetra and Bhysya castes are nearly extinct, and that the Hindoo nation is now composed principally of Brahmins and Soodras, with their subdivisions. These subdivisions are innumerable:—Every trade, every peculiar department of service, has its class, wherefore the retinue of servants to be kept is very large; for the man who carries in your water cannot wait at table, nor the man who cooks a dinner serve it up, nor the who waits at table sweep the room; and the s of classification goes on through all the pursui In a number of instances, Brahmins have soldiers in the service of the East India Comp without engaging in menial employments; and claim precedence even of kings, in point of This rigorous classification of the Hindoos und presents an obstacle to the advancement of Chr which, though hardly thought of by the British is next to insurmountable, and will retard pr for an indefinite period. The Hindoo who b Christian loses his caste by partaking of th Supper, and it therefore requires an extra strength of mind to make a profession of fait gospel; for by losing his caste in this or any o no one will speak to him, or touch him, or intercourse with him—his own wife and family own him—he becomes a Paria, a dog.

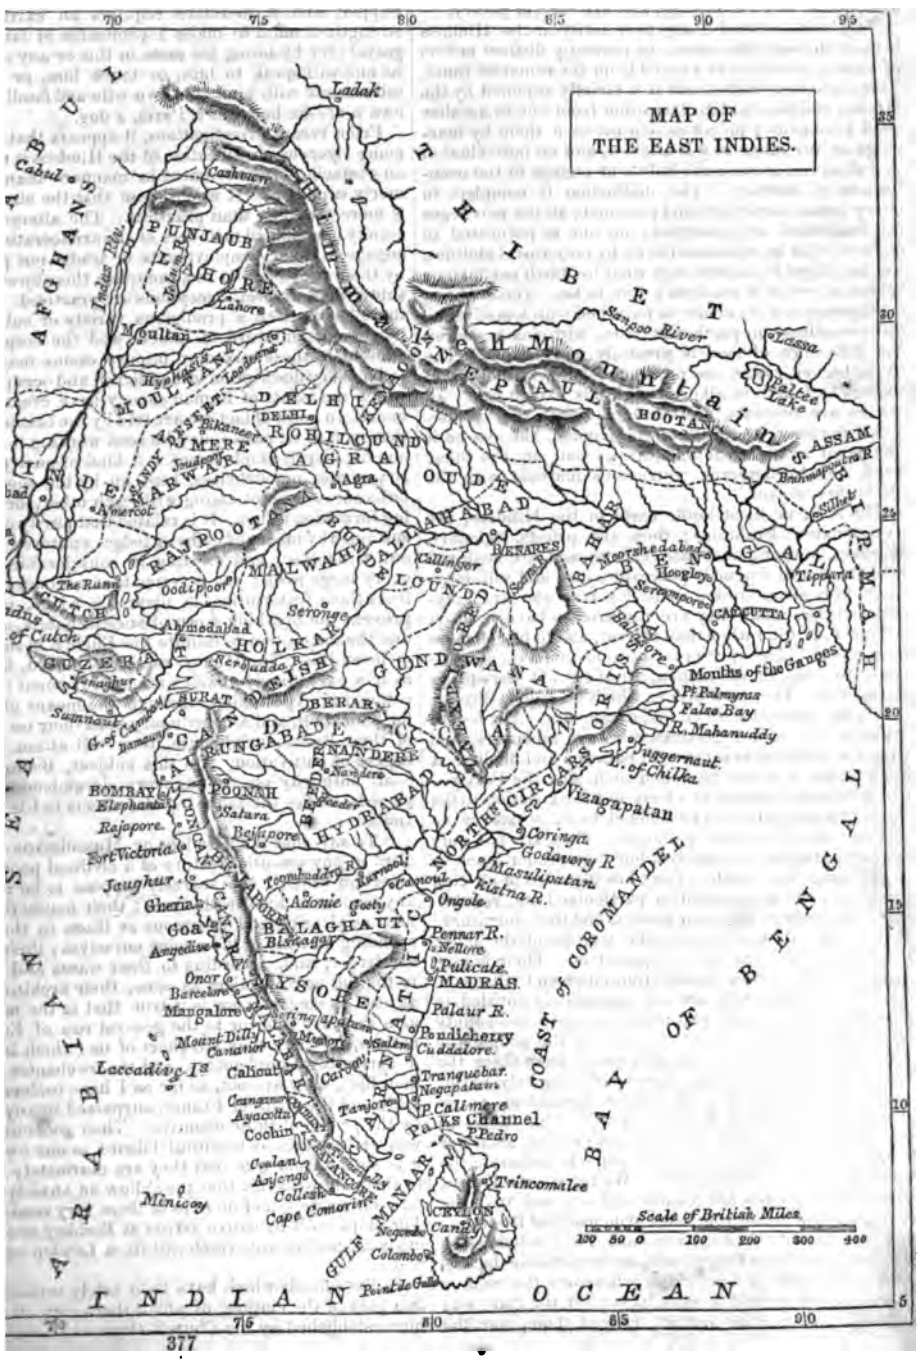
From recent investigations, it appears that going rigorous classification of the Hindoos is n an obstacle to improvement in manners than merly supposed. It would seem that the clas is more theoretic than practical. The altered society has obliged members of the aristocratic engage in divers employments or trades not p by their religion; but to accomplish this object subterfuges and self-deceptions are practised. there have arisen a prodigious variety of sub by the intermixture of castes; and the emp allowed to these mixed or impure castes may to be every description of handicraft and occup which the wants of human society have creat mand. In point of fact, we are told by the best a that men of all castes may be seen working to one handicraft employment. A kind of purity is perhaps, nevertheless, kept up by the me different castes not eating with each other, or ing forbidden things. It is related that purity o sustained by means of clubs or lodges scattered out Hindostan, and existing in considerable every large town; yet it seems that excommu from these fraternities, is, upon the whole, u prevent the breaking down of ancient habits, o due the disposition to imitate the English in th civilised life. The Hindoo races are, indeed, d as now exceedingly anxious for improvement; rational to expect, that, through the means o for education, and a conciliatory behaviour on of their British neighbours, they will attain degree of cultivation. On this subject, Bisho —an authority on whom every dependence placed—makes the following statements in his India:—

"To say that the Hindoos or Mussulmans cient in any essential feature of a civilised peo assertion which I can scarcely suppose to be any who have lived with them: their manner least as pleasing and courteous as those in th sponding stations of life among ourselves; thei are larger, and, according to their wants and to the full as convenient as ours; their archite at least as elegant; nor is it true that in the m arts they are inferior to the general run of E nations. Where they fall short of us (which i in agricultural implements, and the mechanics mon life), they are not, so far as I have under Italy and the south of France, surpassed in an by the people of those countries. Their goldsm weavers produce as beautiful fabrics as our ov it is so far from true that they are obstinately to their old patterns, that they show an anxiet tate our models, and do imitate them very succe The ships built by native artists at Bombay are ously as good as any which sail from London o pool.

In the schools which have been lately establ this part of the empire, of which there are at nine established by the Church Missionary, an

ristian Knowledge Societies, some very unex-
cts have occurred. As all direct attempts to
he children are disclaimed, the parents send
iout scruple. But it is no less strange than
; there is no objection made to the use of the
New Testament as a class-book; that so long
chers do not urge them to eat what will make
: their caste, or to be baptised, or to curse
ıtry's gods, they readily consent to every thing
: not only Mussulmans, but Brahmins, stand
perfect coolness, and listen sometimes with
interest and pleasure, while the scholars, by
the roadside, are reading the stories of the creation and of Jesus Christ.

The different nations which I have seen in India (for it is a great mistake to suppose that all India is peopled by a single race, or that there is not as great a disparity between the inhabitants of Guzerat, Bengal, the Dooab, and the Deccan, both in language, manners, and physiognomy, as between any four nations in Europe), have of course, in a greater or less degree, the vices which must be expected to attend on arbitrary government, a demoralising and absurd religion, and (in all the independent states, and in some of the



districts which are partially subject to the British) a laxity of law, and an almost universal prevalence of intestine feuds and habits of plunder. Their general character, however, has much which is extremely pleasing to me: they are brave, courteous, intelligent, and most eager after knowledge and improvement, with a remarkable talent for the sciences of geometry, astronomy, &c., as well as for the arts of painting and sculpture. In all these points they have had great difficulties to struggle with, both from the want of models, instruments, and elementary instruction; the indisposition, or rather the horror, entertained, till lately, by many among their European masters, for giving them instruction of any kind; and now from the real difficulty which exists of translating works of science into languages which have no corresponding terms."

RELIGION OF THE HINDOOS.

The religious belief of the Hindoos is called Brahminism, and is founded on a most extensive collection of sacred records, of which the Brahmins are allowed to be the sole expounders. "These sacred writings (says Mr Statham, in his 'Indian Recollections') are of two kinds—the Vedas and Shastres. The former may be termed their Scriptures, the latter expositions of them. Beass Muni (that is, Beass the Inspired), a prophet who lived in the reign of Judistheer, on the banks of the Jumna, near the present city of Delhi, collected all the detached pieces which form the Vedas, from all parts of India, and gave them their present form and arrangement. They are divided into four books, all written in the Sanscrit. The first book is called Rug Veda, which signifies the Science of Divination, concerning which it principally treats. The second is distinguished by the title of Sheham, which signifies Piety or Devotion, and this book treats of religious and moral duties. The third is the Judger Veda, which, as the word implies, includes the whole science of Religious Rites and Ceremonies. The fourth is denominated Obater Bah: in the Sanscrit, *obater* signifies the being or essence, and *bah*, good; this, literally interpreted, is the knowledge of the Good Being, and accordingly this book comprehends the whole science of theology and metaphysical philosophy.

The Vedas, as also the Shastres or commentaries, pretend to great antiquity; so much so, that many Europeans have been strangely staggered in their belief of the Mosaic chronology by reading them. But it only requires a little consideration and research to discover a vein of imposition running through the whole of their details. They reckon the duration of the world by four ages, or *jogues*, extending altogether to about eight millions of years; but the fallacy of this reckoning has been fully exposed by astronomical observation.

The idea which the Shastres give of God, is that there is one supreme Being, whom they style Bhogabon or Esher, sometimes Khodah; proceeding from him, are three powers or deities, namely, Bruhmha, the Creator of all; Vishnu, the Preserver of all; and Seeb or Sheva, the Destroyer of all. Now, whilst the latter is worshipped by all, the former has scarcely any attention paid to his temples; and even Vishnu, the Preserver, has few votaries compared with the destroyer Seeb. Subordinate to these are 330,000,000 inferior gods and goddesses, each representing some peculiar virtue or vice. The Hindoos suppose that each of the three presiding powers oftentimes seeks to encroach upon the prerogative of his compeer, and thus are often quarrelling and seeking to subvert each other's arrangements."

One of their most superstitious practices consists in worshipping or deifying the waters of the Ganges. This large and beautiful river extends from west to east across an extensive district in Hindostan Proper, and with its tributaries may be reached by a very large proportion of inhabitants in the most populous and productive part of India. The sacred ceremony of adoring the Ganges consists in the population crowding morning and evening to bathe in it, and quantities of the water are carried to all parts of India sworn by in courts of justice. "At Allaha tinues the above entertaining writer), where th of the Ganges and Jumna unite, the country miles round is considered sacred ground; an is the number of pilgrims who resort thither ing, that the vizier has received in one year of rupees for permission to enjoy the benefit sion in the sacred flood. Many are the lives here annually. The persons who thus fall their superstition are generally females, who all parts of the country to perform the tragic who show a firmness of purpose worthy a be Several of them, accompanied by the priest in a boat, and proceed to the spot where th unite, when each of the victims in succession from the boat to the river, with a large ea fastened to her body, and is supported by a she has filled the pan with water from the str the priest lets go his hold, and she sinks to ris amidst the applauses of the spectators, whilst mins enjoy the scene, and extol the fortitude victim to her who is about to follow."

The cow is an animal held sacred among doos, and cow-dung is used in the temples places as a species of holy ointment. The lot with tall luxuriant leaves, is likewise held in ration. Some of the temples or pagodas of th are of high antiquity and gigantic conception appearance, and tasteful architecture. The always made in a huge pyramid, in a number which gradually grow narrower as they app top. Inside may be seen the cow lying down, or some other object of adoration. Here sacr place. One of the most extensive pagodas that of Juggernaut, whose towers are seen miles' distance. Here, as at other places, processions of idol cars, large heavy ornamen tures, which are dragged along by the multi the shouts of assembled thousands. As the w swiftly on, self-devoted victims rush forwa themselves before them, and are crushed exulting in the hope of thus securing a pass celestial abodes. The practice of widows themselves on the funeral pile of their hus another horrid rite; but it has been suppres cent times by the British government.

Besides Brahminism, there are a variety of beliefs and sects in India, but all less or mor on the most gross superstitions. Each pos own temples, images, and orders of priestho Boodhists, previous to their violent expulsi Hindoos, were second in point of numbers; religion is now little known in India, and is chiefly to Thibet, Birmah, Siam, and Ceylon.

INDIAN LANGUAGES.

There are, it is believed, four original lan India, and of these there are some hundreds o differing less or more from each other and originals, and maintaining also a partial distinc the introduction of Arabic, Persic, and othe words. While, however, each tribe has its o liar dialect, all use one language, the Sanscrit sacred writings. The Sanscrit is a dead languag probably once spoken; it is wonderfully perf construction, and extremely copious. Its al called *Devanagari*, divine alphabet, because to have had its origin from the gods, whose it is; it consists of fifty letters, and has three The next language in estimation is the Prace comprehends the various dialects used in comm ing and social intercourse. The dialects of th are spoken in Bengal, and include that which Hindostanee, the principal spoken tongue in I

MAHOMMEDANS AND OTHER CLASSES.

According to Mr Hamilton, "the modern medans may with safety be estimated at on

total population; and notwithstanding the sub- of their political predominance by a Christian their religion continues to expand. They are er, however, the sanguinary zealots who, eight d years ago, in the name of God and the prophet, desolation and slaughter among the unconverted . Open violence produced little effect on so a people; and although the Mahommedans sub- tly lived for centuries intermixed with Hindoos, ical change was produced in the manners or of the latter; on the contrary, for almost a cen- st, the Mahommedans have evinced much defe- o the prejudices of their Hindoo neighbours, and g predilection towards many of their ceremo- The warlike portion of the Mahommedans hav- ently been dislodged by the British from the tta courts, where they had found shelter, they een obliged to seek employment in inferior sta- The Mahommedans of India are more intelli- nd possess greater strength and courage than ndoos; but they are also more proud, jealous, re- l, and rapacious, and their fidelity is much less n by the British government. In some districts hommedan population is nearly as numerous as the Hindoos, and both seem to live in a state of amity.

les the Hindoos and Mahommedans, there are scattered tribes in India, of a very different er from either, and often inhabiting mountainous f country, and called Garrows, Monguls, Tartars, mong the different races is found that of the s or Persians, the ancient worshippers of fire, ce driven from their native country by the per- g sword of the Arabs. Many of this people are , and they take the lead in the commercial tran- s of Bombay, Surat, and other north-western Their general conduct is quiet, orderly, and able.

rithstanding what has been related of the strict- the Hindoos regarding modes of living, they iable to fall in with European usages. In Cal- nd other large towns, many of the wealthy imitate the British in their dress, household re, equipages, and style of living, and show a desire to mix in their social parties, to which, r, they rarely find access. The English take s to conciliate the friendship of the native tribes, er well behaved and intelligent they may be. his foolish, surly, national pride (says Bishop), I see but too many instances daily, and I am ceed it does us much harm in this country. We t guilty of injustice, or wilful oppression, but we ut the natives from our society, and a bullying, nt manner is continually assumed in speaking to " The exclusiveness of this species of hauteur is ps fully more remarkable with respect to that of persons who have drawn their origin from the ourse betwixt the English and natives. These British, as they are called, form a part of the lation of Calcutta, and are a very interesting and sing people. "Many of them (says Statham) ery opulent, and others can vie with the more ited of their European neighbours in literary inments; notwithstanding this, there is a marked mpt shown them by Europeans generally. If a pean lady should wed with an Indo-Briton, the s of all the higher circles would be closed against however rich the man of her choice might be." state of things will happily be modified by the isions of the act of Parliament already narrated.

RURAL CHARACTERISTICS AND PRODUCTS.

the large and fertile territory of Bengal, as well all other parts of India where the cultivation of il is pursued, the art of the husbandman is, as be expected, still in the rudest state; and in every er there exists great room for improvement, which ng could so well facilitate as the settlement of igent European families. In the inundated dis- tricts of Bengal, rice is the main crop which is raised, at least during the wet season: it grows to its greatest height while the lands are overflowed, and is frequently reaped by men in canoes, the ear only being cut off, and the stalk left. When the peasants go to market during the height of the flood, they take their families with them, lest the house should be washed off during their absence with the boats. Rice is the summer crop, requiring much heat and moisture; but during the cool dry season, from November to April, they sow and reap another harvest, consisting of wheat, barley, or different kinds of pulse: this is called the *dry crop*, because it is reared without flooding the lands; the rice being considered as the *wet crop*, for a contrary reason. There are, therefore, two seedtimes and two harvests in this rich country. Besides these regular crops, many small grains are sown, which are limited to no particular season of the year, and which reward the industry of the Indian cultivator with a rich vegetation at all times.

Besides the different kinds of grain, the farmers of Bengal raise a number of other products, of great value. Of these, one of the principal is indigo: this is a small plant, shrubby in its growth, but in its leaves and flowers very much like the common tares of this country; it is sown during the rains, and raised in rows or drills. The leaves only are useful, on which account it is cut repeatedly, without being allowed to flower, which would make it drier and less juicy. The leaves are steeped and beaten in a vat among water; after which the liquid is strained through cloths, and set to evaporate in shallow troughs placed in the shade. This is soon effected in that warm dry climate; and the indigo is then found deposited in a crust at the bottom. The process requires much preparation and expense; and it has only succeeded well since the country has enjoyed peace, and there has been a prospect of employing large capitals with security. It now produces, however, a large return to the cultivators; and gives a new source of wealth to the country. It is cultivated along the whole course of the Ganges up to Delhi, and is an annual in the lower, but a triennial in the upper provinces. It succeeds best on overflowed grounds, and in dry seasons is apt to fail. The number of factories of indigo in the Bengal presidency is estimated at 300 or 400. A few of them belong to natives; but they are chiefly in the hands of Englishmen, who take leases of ten or twenty thousand acres of land in the name of native servants (not being allowed to hold it in their own) from a zemindar, for the purpose. They encourage the ryots (native cultivators) to raise crops of the plant, by making advances to them in money. They purchase the produce at a price agreed on, and erect works for extracting the dye from the plant; the whole of the operations being generally conducted by native labourers, under native superintendants. It is observed that the establishment of such factories raises the value of land, extends cultivation, and spreads a certain degree of improvement in the villages. The importation of Bengal indigo into Britain began about forty years ago, and has since increased to an amazing extent. Mr Crawfurd calculates that about 9,000,000 lbs. are annually exported from Calcutta, of which 7,000,000 lbs. come to Britain, and the rest goes to America, France, Germany, Sweden, &c. About £1,680,000, he thinks, are expended for rent and labour in its production, and it realises in Europe a sum of £3,600,000. In the countries named, Bengal indigo is silently obtaining a preference over every other.

Silk is raised in great quantities in Bengal and Orissa, between the latitudes of 22° and 26°, and it has hitherto been very nearly a monopoly in the hands of the Company. It is chiefly produced by the native Indian worm, which affords four crops, or sometimes six in the year: the Italian worm, which was introduced half a century ago, yields only one crop a-year, but of a finer quality. The Indian silk, compared with the best European varieties, is "foul, uneven, and wants staple;" but its cheapness has brought it into extensive consumption.

The Company have eleven factories, or "filatures," which form the centres of "circles," within which the cultivation of silk is carried on, each having a certain number of subordinate stations. The silk, in the raw state, is purchased from the ryots at the factories or sub-factories, wound off the cocoons, and prepared for transmission to Europe. About 1,800,000 lbs. are annually brought to England, of which a very small quantity (one per cent.) is equal to the finest silk; the mass of it is decidedly inferior. There is strong ground to conclude that, under the new act, the production of silk in India will be greatly increased, and its price in Great Britain lowered.

Cotton has long been cultivated by the natives in all the three presidencies. It is universally of the kind called "short staple," and being coarse in quality, and badly cleaned, it fetches only two-thirds of the price of American short staple in the British market. The best quality comes from Bombay (the Guzerat); the next from Madras; and the worst from Bengal. The cultivation being entirely in the hands of the natives, is rudely conducted; and, in particular, pains are not taken to renew the plant constantly from the seed, as the Americans do with the most advantageous results. Experiments have been made under the sanction of the Company, and by private individuals, to introduce and cultivate finer species than those in use, but they have generally been failures. There is no doubt, however, that by the introduction of European capital and skill, the quality of Indian cotton may be much improved, and what is raised sent to the market in a much cleaner and better condition. The exports of cotton from India to all countries amounted in 1827 to 68,000,000 lbs., of which only a third part came to Great Britain.

The cultivation of the sugar-cane is pursued with great success in Bengal and other parts of India, but chiefly by the natives, for domestic use. The process of bruising the canes is on a rude plan, and the sugar which is produced is from this or some other cause very inferior to the sugar of the West Indies. In no article of produce is there greater room for improvement than in this. The cultivation of the cane requires great care and skill, and the mechanism for extracting and preparing the sugar can only be erected at a great outlay of capital. It is anticipated that when Europeans are permitted to hold lands freely, and to embark capital on sugar plantations, sugar of good quality may be manufactured much cheaper than in the West Indies, where the price of labour is much higher.

The bamboo, a species of cane or reed, is much cultivated in Bengal. It grows to the amazing height of forty feet; and though it arrives at perfection in two years, it has all the firmness of the hardest timber. It has joints like a reed, or like grass, and is, like them, quite hollow; yet it is so strong that the porters of the country use it for suspending the heaviest burdens between their shoulders. It is used for beams and uprights in building houses; and being protected from damp by a kind of natural varnish, it will last in such situations for a hundred years. It serves also for making bridges, for the masts of small boats, and for innumerable other purposes; yet of this useful material, one acre of land will yield ten times as much as the same space will produce of other wood. None of the productions of India puts so many conveniences, in regard to furniture, houses, boats, &c., within reach of the poorer classes, as the bamboo. It would require a large space to mention even the names of the plants useful to man, which flourish in the luxuriant soil of Bengal. Cotton, tobacco, the opium poppy, rape (which is cultivated for the sake of its oil), cucumbers, vegetable marrow (as one of the gourd tribe is called), and innumerable other plants, always afford a plentiful harvest. Of fruit-trees, there are the mango, which is something like our peach, the date-tree, the vassia, the guava, the pomegranate, and others. Another production, which is peculiar to warm climates, and which grows in high perfection along the sea-coasts, is the cocoa-palm. This tree would of itself be almost sufficient for the subsistence of mankind in the countries where it grows, so various and useful are its products; indeed, there are some populous islands—the Maldives and Laccadives—on the coast of India, where little else is cultivated.

In the interior of India, the tea-plant is said to flourish, and is likely to become of great importance to the trade of the country. Districts lying between the 26th and 28th degrees of north latitude, and the 94th and 96th degrees of east longitude, are described as possessing this shrub in abundance, and of a quality equal to that of China. In Assam, which lies between Bengal and Thibet, the attempt has lately been made to cultivate and gather the product of the tea-plant for purposes of commerce. In 1838, ninety chests of it were imported into London, and found to be of a good quality. Persons skilled in the gathering and preparation of the leaves have been introduced from China; and there seems little reason to doubt that Assam is capable of producing tea to any extent, if sufficient capital and enterprise were exerted in the undertaking.

ANIMALS.—CLIMATE.

India possesses a variety of animals, both quadrupeds and birds, which are found in no other region. Among the quadrupeds, the most conspicuous is the elephant, which affords amusement in the hunting, and which is of great service, when tamed, in carrying persons on its back, in an ornamental and commodious seat fitted up for the purpose. The tiger is found in the low marshy regions, or jungles, and is also made the object of hunting; but this ferocious animal is now becoming of rare appearance, except in the remote parts of the country. India abounds in monkeys, and has some peculiar races of dogs. When English-bred dogs are taken to the country, they speedily degenerate. In the forests, deer of different kinds, and a race of antelopes prevail. There are also various descriptions of oxen, among which is the white or sacred bull and cow. There are many splendid specimens of birds, as shining creepers, the ring-necked paroquet, lories, cockatoos, parrots, and other highly coloured feathered animals. There are likewise vultures, bustards, peacocks, and nearly all the game birds and poultry of Britain. India and its islands possess many dangerous reptiles, as crocodiles, lizards, and poisonous serpents or snakes, all of which are more or less found about rivers and marshes, and render bathing in the waters by no means safe. India has also many remarkable insect tribes, one of which, the kermes, produces a fine scarlet dye. Fish, of an immense number of varieties, abound in all the streams and waters, and are frequently of exceeding brilliancy in colour.

The climate of India, though in some high districts salubrious and pleasant, is, on the whole, ill suited to the constitutions of Europeans. There are three seasons—the rainy, cold, and hot: the rainy in general extends from June till October; the cold from November till February; the hot from March till May. During the rains the climate is unhealthy. The temperature of the atmosphere ranges during the hot months from 72° to 105°. At Calcutta, the temperature varies throughout the year from 69° to 89°, but is more commonly about 82°. At Bombay, the temperature is generally somewhat higher; and at Madras it is higher still, the Carnatic being a dry and hot region. This general hotness of India, and the insalubrious character of the rainy season, produces not only discomfort, but renders Europeans liable to fevers, diseases of the liver, and other complaints not common in England. To accommodate invalids, the East India Company have fitted up sanatory stations at certain parts of the country, on the higher grounds, where the air is cool and agreeable; but these places cannot always be depended on by the enfeebled functionaries of the Company, and visits to England are often necessary for the preservation of life. In consequence of the heat of the climate, Europeans amply provide themselves with light cotton garments, which are universally worn as undress.

n made in and about Calcutta, jungles being cleared
ay, streets drained, and stagnant water removed.
ough the situation of Calcutta has not been well
sen, it is excellently adapted for commerce. At
h water the river is here a full mile in breadth.
e advantages possessed for inland navigation are
siderable; foreign imports may be transported with
at facility, on the Ganges and its tributaries, to the
th-western quarters of Hindostan, while the valuable
ductions of the interior are received by the same
annels. There is at all times a vast quantity of
rchandise deposited at Calcutta, and the trade car-
d on is now very extensive. Besides a government
nk, there are three private banks, which circulate
a considerable amount. There are several daily,
ee-a-week, and weekly newspapers published. The
ligious, and charitable, and educational institutions,
numerous and of great service. Society in Calcutta
ay and splendid; and the British inhabitants among
ir own class are described as hospitable, though
lous of etiquette, and of an overbearing disposition.
ere are no hotels, or inns, or lodging-houses of any
cription—a want which appears perfectly amazing
nd all strangers, male or female, must be provided
h introductions to the houses of residents. The
enses of living are very considerable; and as there
now no more opportunities of acquiring wealth by
spoliation of native principalities, fortunes are much
lomer realised than formerly. There being also
w fewer deaths, there are fewer chances of promotion.
cording to Mr Hamilton, "Without being attached
some department of service, or trained up to some
chanical trade, there is little hope of prosperity to a
ng man migrating on chance from Europe. Here
the inferior situations of clerks, overseers, &c., are
essarily occupied by the natives; and it is by these
dations in Europe that young men rise to opulence
the commercial world." The population of Calcutta
composed of about 14,000 Christians, 48,000 Mahom-
dans, and 120,000 Hindoos; but this is the amount
y within the city proper. If the environs or suburbs
included, the population will amount to perhaps
,000; and so densely peopled is the surrounding
rict, that within the circuit of twenty miles there is
opulation of nearly two and a half millions.

Serampoor, a Danish settlement, about twelve miles
ve Calcutta, is the head-quarters of the missionaries
t from Europe, and here a printing-press has been
blished, from which Bibles in a great variety of
guages have been issued. The missionaries also
e conduct a college for the education of native
ristians, Hindoos, or Mahommedans. The enterprise
l judicious exertions of the missionary body at this
ce cannot be sufficiently commended.

Madras, the seat of government of Southern India,
situated in the Carnatic, on the shore of the Bay of
ngal, in latitude 13° 5′ north, longitude 80° 21′ east.
e shore is here low, and dangerous to approach by
sels. On the beach stands Fort St George, a place of
siderable strength, and which may be easily defended
a small garrison. A noble range of public edifices,
luding a customhouse and court-house, also adorn
at is called the north beach. Madras differs in ap-
arance from Calcutta. It has properly no European
n, the settlers residing in their houses in the midst of
dens, and transacting business in the district appro-
ated to the residence of the natives. The principal
urch in Madras, St George's, is a beautiful edifice.
ere are many excellent charities here; and the school
male and female orphans, into which the philanthro-
Dr Bell introduced the Lancastrian system of edu-
ion, is superior to any thing of the kind in Calcutta.
e society of Madras is more limited than that of Cal-
tta, but the style of living is similar. The roads in the
inity are excellent, and afford most agreeable drives
the European residents. According to Heber, "the
tive Christians are numerous and increasing, but are,
fortunately, a good deal divided about castes." The
menians are here numerous, and some of them

wealthy. A Scotch Presbyterian church is now erected. The population of Madras and its suburbs has been stated at upwards of 400,000.

Bombay, the seat of government for the western parts of India, is a small rocky island, lying on the west coast of Hindostan, in latitude 18° 56′ north, longitude 72° 57′ east. Bombay was originally some hilly rocky islets, but these, by the influence of the high tides, have been joined to each other; and now the island is composed principally of two unequal ranges of whinstone rocks, extending from five to eight miles in length, and at the distance of about three miles from each other. All the ground that can be cultivated is now laid out in agriculture, and the remainder is either barren or covered with the residences of Europeans and natives. These residences are on wet, low, and unhealthy grounds, ever below high-water mark; and from this and other circumstances, Bombay is described as being the most insalubrious of the presidencies. The fort of Bombay is situated at the south-eastern extremity of the island, on a narrow neck of land. The chief advantage of Bombay is its deep tide water, which permits the most extensive system of maritime trade: excellent docks are erected for the accommodation of the shipping. Bombay is the seat of very extensive trade with the Persian Gulf on the north, as well as with the south of India. Cotton is the principal article of export. The population is stated at about 160,000, composed of Christians, Jews, Mahommedans, Hindoos, and Parsees.

Delhi, once the capital of the Mogul empire, is situated in 28° 41′ north, in the province to which it gives its name, and at the distance of 976 miles from Calcutta. This once magnificent city is said to have, in former times, covered a space of twenty square miles; in the present day an immense number of its ancient streets, houses, temples, and other edifices, are in ruins, and the modern town, removed at some distance from the old, occupies a space of seven miles in circumference. It is seated on a range of rocky hills, and is surrounded by walls, recently improved and strengthened by the British. The city contains many large and good houses, mostly built of brick. There are a great number of mosques, with high minarets and gilded domes, and above all are seen the palace of the emperors, a very high and extensive cluster of Gothic towers and battlements, and the Jumna Musjeed, the largest and handsomest place of Mahommedan worship in Hindostan. The chief material of these public buildings is red granite, of an agreeable colour, inlaid in some of the ornamental parts with white marble. One of the principal characteristics of Delhi is thus described by Bishop Heber:—"We passed, in our way to the Agra gate, along a very broad but irregular street, with a channel of water, cased with stone, conducted along its middle. This is part of the celebrated aqueduct, constructed, in the first instance, by Ali Merdan Khân, a Persian nobleman in the service of the Emperor Shahjehan, then long neglected during the troubles of India and the decay of the Mogul power, and within these few years repaired by the English government. It is conducted from the Jumna, immediately on leaving its mountains, and while its stream is yet pure and wholesome, for a distance of about 120 miles; and is a noble work, giving fertility to a very large extent of country near its banks, and absolutely the sole source of vegetation to the gardens of Delhi, besides furnishing its inhabitants with almost the only drinkable water within their reach."

The British resident at Delhi exercises a most extensive authority, from his having the exclusive charge of the emperor and his family, his taking cognisance of all political events in the north-west of India, and his superintendence of many ex-kings and chiefs. The office is therefore always filled by one of the ablest and most experienced of the public functionaries of the Company. The population of Delhi is now computed not to exceed 200,000.

Agra, the capital of the province of the same name, is commodiously situated on the south-west side of the river Jumna, in latitude 27° 11′ north. The greater part of this once flourishing city is now in ru the habitable part, the houses are several st height, and the streets remarkably narrow. a large and ancient fort, surrounded with h and towers of red stone, which commands sor views of the city and its environs. The princip according to Heber, are the Motee Musjeed, ful mosque of white marble, carved with exqu plicity and elegance; and the palace built b in a great degree of the same material, and co some noble rooms, now sadly disfigured and d by neglect. Agra has been in some measure r by the British; and when made the seat of a pr will most likely be still further improved.

Benares is an ancient and highly venerate Hindostan, situated in latitude 25° 30′ north elevated piece of ground on the banks of the about half-way betwixt Agra and Calcutta. Th of this holy city are extremely narrow, and th which rise to the height of six storeys, are in so united by galleries. The number of stone a houses from one to six storeys high exceeds and the mud houses are about 16,000, beside houses. The number of inhabitants is estim upwards of 600,000, exclusive of a large body porary residents, who come hither for religi poses from all parts of India. Benares may the university town of the Hindoos, as their religion are here taught by Brahmins and lear in various establishments for the purpose. reckoned to be a place of extraordinary sanct to die at Benares is the greatest happiness of a because he is then sure of immediate admis heaven. The town is distinguished by a ma temple dedicated to Siva. From its great a relics of former greatness, and religious el Benares may be considered the most interestin India.

PORTUGUESE SETTLEMENTS.

The possessions of the Portuguese in India confined to Goa, and a small territory round it; D a sea-port in the province of Guzerat; Diu, island near the southern extremity of the Guze insula; Dhelli, on the island of Timor; also M China; and establishments on Sumbhawa, Flo some others of the Eastern Isles. Goa is the on here worthy of notice. It is situated on the we of India, in the province of Bejapoor, in latitud north, 250 miles south-east of Bombay. Du period of Portuguese dominion in India, this w splendid and populous capital, the head-quarters tyranny, the seat of their inquisition. It is now ness, of which the monasteries form the only portion, and a few miserable monks, half of them are the only inhabitants. "Indeed (says Mr H the city may be traversed from one extremit other without meeting a human being, or any oth of former population than pavements overgro grass, gardens and court-yards choked with und and princely dwellings and venerable abbeys mo rapidly to decay." There are still several chu preservation, also the building once occupied inquisition, which has been shut up for many Panjim, or New Goa, is situated five miles ne entrance to the harbour of Goa, and is now the the Portuguese authorities, and of the business on. The territory in the neighbourhood of Go miles in length by twenty in breadth, forms the sion of the Portuguese; and it was estimated, that within this tract there were two hundred c and chapels, and above two thousand priests.

INDIAN ISLANDS.

The islands usually considered to belong to both from proximity and similarity of social co are Ceylon, Sumatra, Java, and Borneo, with t luccas and a great number of smaller size. lying between 5° 50′ and 9° 50′ north latitude, a

vers their head and back. All processes of manu-
cture and handicraft are on the rudest possible scale,
d carried on without what we term capital. The
ople only scratch the ground instead of ploughing it;
y never apply any manure; their corn is thrashed
setting bullocks to tread upon it; the smith's anvil
the nearest stone, his bellows a rough goat-skin; a
nemaker tans the raw hide one day, and makes shoes
it the next, sitting the whole time at the door of his
stunner; the weaver's apparatus needs but the shadow
a tree for shelter—and it can be removed at an hour's
tice to any other tree which is more convenient.
en their distillery needs only an earthen kettle, some
d water, and a few bamboo reeds for a worm; and
h these they produce liquors as intoxicating and
ricious as any manufactured by the science of
rope. This absence of skill in all the processes of
dustry, renders the labour of the working man of
y slight value; hence, he never receives more than
at is barely necessary for subsistence; and the whole
es of the people are consequently at the lowest ebb
regard to domestic accommodations or mental ac-
irements. Their celebrated countryman, Rammohun
y, who died lately in this country, believed that many
them did not know whether the British or the Ma-
mmedans were masters of India.

Simple as the bulk of the population is, there are not
nting scattered tribes and families dexterous both in
ming and crime. Skill in jugglery, or sleight of
nd, has been carried to a pitch never elsewhere
alled, and the tricks performed are so wonderful as
confound the sagacity of the most acute Europeans.
anquillised as the country is in its civil affairs, there
still a great want of police or effective local jurisdic-
n. In the accounts of all travellers, it is mentioned
t there is no possibility of travelling in almost any
t of the interior in safety without a guard and re-
ue of servants. The roads, if they can be called
h, are hardly discernible tracks, quite unfitted for
eel-carriages, and travellers must therefore ride on
rseback, or on the backs of elephants, or be carried
palanquins—a species of litter supported on men's
ulders. There being also no inns in India, each
veller is obliged to carry tents and provisions for
y use.

n the states of Bhopaul, Oude, Gwalior, and Bundel-
nd, and the Company's possessions in the Doab, as
l as in some other quarters, there exist hordes of
tches, called Thugs, who infest the roads, and carry
a methodic system of murder, for the sake of plunder.
y kill by strangling their unhappy victims. The
gs form a peculiar race, and practice their murders,
s alleged, from a religious principle; at all events,
attach no idea of criminality to the offence. They
e practised the trade for centuries, and are with
culty restrained within bounds by the European
ers.

lavery prevails in Bengal and some other parts of
ia, but neither to a great extent nor on a severe
ciple. The slaves are mostly used in domestic
our, and are generally treated with kindness, both
Hindoos and Mahommedans. Although the British
rnment does not countenance slavery, it would be
nd almost impossible to extirpate it, either by law
dmonition, for it originates in the sale of children
parents during famines, or under circumstances of
liar calamity. Such is sometimes the distress of
parents, that they will dispose of their offspring for
merest trifle, not from want of affection, but most
y with a view to the saving of their lives. Selling
dren into slavery, therefore, prevents infanticide, or,
t is as bad, death by starvation; and so long as no
l exists to relieve the famishing natives during
s of exigency, it does not seem possible to prevent
disposal of children by their parents, especially
e the laws of the Hindoos permit the practice. We
, however, naturally expect that, with the advance
ivilisation and habits of carefulness, slavery will
, as elsewhere, cease. At present, slaves in India

are frequently liberated by their owners from motives of piety.

Independently of the efforts of the Bishop of India and the religious establishment with which he is connected, the Church of Scotland and other bodies of Christians have for some years been putting forth their exertions to attempt the conversion of the native pagan races, and consequently to elevate their condition. But on the whole, very little success has crowned their well-meant labours; the loss of caste, which inevitably follows the abandonment of the Hindoo faith, may be stated as a barrier to conversion which no power of persuasion can remove; in short, it has been proved beyond the possibility of doubt, that to Christianise India, the people must in the first place be instructed in secular knowledge. Aware of this fact, attention is beginning to be directed to the education of the young. Fortunately, the general population throughout Bengal and Bahar, where investigations have been made, are zealously anxious for instruction in useful knowledge, as well as to learn the English language; and there is a prospect of a plan of education being carried into effect, on the basis of native schools already in existence.

From all that we can learn, it would appear that the present rude state of learning among the native population is a degeneracy from something of a lofty character in ancient times. It seems beyond a doubt, that, some thousands of years ago, there was as enlightened a race of inhabitants in Hindostan as there was about the same period in Egypt. Certain remains of art are on a truly gigantic and splendid scale. The most celebrated are the temples of Ellora, a town near Aurungabad, 260 miles from Bombay. They are said to extend over a circuit of three leagues, and consist of stupendous edifices sculptured in the solid rock, like the most exact and beautiful architecture. They are generally about 100 feet high, 145 feet long, and 62 feet wide; and contain thousands of sculptured figures, including sphinxes and other objects similar to those now seen among the ruins of Egypt. The history of these now deserted temples is entirely lost, and imagination wanders in quest of their remote and mysterious origin.

Turning from such matters to others more intimately connected with the modern condition of affairs, it is gratifying to anticipate that British capital and skill will speedily be directed in India to the cultivation of sugar, coffee, tobacco, and particularly cotton, all which products, from the extraordinary cheapness of labour, may be increased to an incalculable extent, and with the most enlivening prospect of profit. Hitherto the system of jurisprudence established by the Company has been a vain mixture of Hindoo, Mahommedan, and English law, and by no means well calculated to preserve public tranquillity. Should the government proceed to modify and extend the system of administering the laws, at the same time relaxing the burden of taxation on land, and endeavouring to conciliate the natives by promoting those worthy of trust, much good might be anticipated. By these and other measures, suited to the genius of the people, a solid basis would be afforded for the investment of capital, and India would gradually improve both in its moral and physical condition.

Until within the last few years, the intercourse with India was carried on by means of vessels belonging to the East India Company or private traders, which made the passage in about five months by the Atlantic and Cape of Good Hope. This most tedious route is still pursued by trading vessels; but the more expeditious route by the Mediterranean, Egypt, and Red Sea, to Bombay, with concurrence of Mehemet Ali, is adopted for mail conveyance and passengers who desire a quick transit. The line pursued is London to Paris; Paris to Lyons and Marseilles; thence by steam-boat, touching at Leghorn and Naples, to Malta; and by another *steamer from Malta to Alexandria*; from Alexandria *by canal to the Nile*, and onwards by boat to Cairo; thence by a land journey to Suez; down the
from Suez to Bombay, touching at Moch
length of time from London to Bombay,
days. The expense of a single traveller is
£153, 19s. 9d.

The circulating medium of India consists of
silver coins, paper-money, and cowries. T
common silver currency is the new coinage of
Potdars, or money-changers, are a common

following is their value in Calcutta:—4 cowri
da; 20 gundas 1 pon; 32 pons 1 current rupe
shillings sterling (2560 cowries); 10 curren
1 pound sterling. The sicca rupee is 16 per
in value than the current rupee, which is an i
coin. The Bombay rupee is valued at 2s. 3
goda is 8s. The British government now s
handsome and commodious coinage, the more
silver coin being the rupee, which nearly resem
half-crown.

An idea of the trade with India may be obtai
the following statements:—The leading articl
port to India from Britain in 1832, were cott
factures, valued at L.1,531,000; cotton twist
L.309,000; woollen manufactures, L.237,000
wrought and unwrought, L.364,000; iron,
and unwrought, L.144,000; hardware and
L.82,000; wines, L.150,000; beer and ale,
glass, L.101,000; stationery, L.50,000; books,
linen manufactures, L.49,000; jewellery, L.33,
manufactures, L.125,000; apparel, L.32,00
of the other articles is under L.30,000. To
of the articles exported, L.3,750,000. In
cluding those to Ceylon, the total expo
L.3,876,196.

The leading articles of import from India
were—indigo, L.1,242,000; raw silk, L.1,189,00
wool, L.807,000; saltpetre, L.413,000; coffee, L.
sugar, raw, L.209,000; dyed cotton, L.136,00
calicoes and muslins, L.49,000; rice, not
L.128,000; pepper, L.70,000; tortoise-shell, L
Each of the other articles was under L.45,000.

The following words are frequently used in r
to India:—

Adawlet, a court of justice.—*Bega*, a land
amounting in Bengal to about the third of an
Bungalow, a dwelling formed of wood, bambo
and other light materials.—*Chokeydar*, a watch
Choultry, a place for the accommodation of tra
—*Circar*, a large division of country.—*Coolies*,
ers, or porters.—*Coss*, a measure of distance
than a mile, nor more than two miles.—*Crore*,
lions.—*Dacoits*, robbers.—*Dewan*, a head office
ance.—*Dewanny*, the privilege of exacting taxes
petuity.—*Durbar*, a court of audience.—*Gentoo*,
tuguese term, signifying a Gentile.—*Ghaut*, a
hills, or pass among mountains.—*Howdah*, the s
vated on the back of an elephant.—*Lac*, one h
thousand.—*Lascar*, a native sailor.—*Lootie*, a plu
—*Musnud*, a throne.—*Nabob*, or *Nawaub*, a
governor under the Mogul empire.—*Paddy*, ric
husk.—*Pagoda*, a word of Europeans for a
temple.—*Perwana*, a license.—*Pergunnah*, a
number of villages, or tract of country.—*Pe*
leader.—*Pundit*, a learned Brahmin.—*Raja*,
or prince.—*Rajpoots*, literally, the offspring o
now meaning persons of distinction.—*Soubah*, a
of twenty-two circars.—*Subahdar*, the governor
roy of a soubah.—*Tiffin*, a lunch, or mid-day
Vakeel, an agent or ambassador.

; again, for as many days, he will be hemmed
een precipitous mountains of the same naked
r, and as unvaried in their appearance as the
and, lastly, ten or twelve days' sail among lakes,
, and morasses, will complete the catalogue of
nous uniformity. There is a constant succession
villages, towns, and cities, with high walls, lofty
nd more lofty pagodas; large navigable rivers,
nicating by artificial canals, both crowded with
or passengers and barks for burden, as different
ch other, in every river and every canal, as
all different from any thing of the kind in the
he world." One general feature, however, per-
e empire—the utter nakedness of the country
cts trees and hedges.

limate of China embraces almost every degree
hermometer. In Canton it ranges from 80 to
es during the summer, but the winter months
ol that many of the inhabitants use fires. There
o more certain criterion of the climate of any
than its vegetable productions, and we may
e mention here generally, that within the bounds
are all the varieties of tree, shrub, flower, and

herb, to be found growing in every other country of the world. The temperature, however, may be generally described as rather warm than cold; but it is much affected by the direction of the winds, which may be literally said to "box the compass," with uniform regularity, during the various seasons of the year. They blow from the north and north-east in October, November, December, January, February, and March, during which months the weather is rather cold; in April and May, from east and south-east, when it is milder, but still cool; in June and July, from the south and south-west, when it is hot; and in August and September, from the west, when the temperature is oppressively sultry and hot. Speaking summarily, the coldest months are November, December, and January; the warmest July, August, and September. Canton, although situated in the same parallel of latitude as Calcutta, is so much cooler during the winter months, that fires are generally used; nay, ice has frequently been found at Canton of the thickness of a dollar, but snow is never or rarely seen. The air is generally dry during the north, moist during the south, and clear during the west winds. The north winds are the most violent, and the south the most feeble. In the months of July, August, and September, the hurricanes, called by the inhabitants *Tay-fun*, usually occur, which, although extremely violent, and coming in sudden gusts, seldom occasion much disaster, owing to the inhabitants being prepared for them. The climate of China is, on the whole, highly salubrious; and many of the complaints common to the whole of Europe are there unknown. The Chinese profess to be free from stone, gout, and gravel complaints; and they are at all events seldom affected with cutaneous diseases. Much, doubtless, is owing to their uncommonly temperate mode of living, of which we will have occasion to say more hereafter. Epidemic fevers, however, are very frequent and fatal, arising from the crowded state of the towns and numerous swamps. The small-pox, too, was formerly very destructive, from the characteristic prejudice of the Chinese against all foreign innovations, however beneficial in the mode of treatment. Their physicians pretended to distinguish *forty* different kinds of small-pox; and when a favourable sort appeared, they endeavoured to propagate it, not by inoculation in the usual mode of incision, but by inserting into the nostril a little cotton wool dipped in the *virus*, or putting on the clothes of the infected! Of late years, however, the European mode of vaccination has generally been adopted, and at the present moment has perhaps entirely superseded the ancient practice. Sore eyes, and even total blindness, are very common, and are undoubtedly to be ascribed to their low, crowded, and smoky habitations, conjoined with their practice of bathing the face in warm water even in the hottest of the summer months.

Several parts of China have suffered much from earthquakes; but there is no appearance of volcanic eruptions throughout the country, though various substances of that description are found in some of the islands along the western and southern coasts.

HISTORY.

From the grossly fabulous and exaggerated nature of the Chinese records, an air of doubt has been thrown over all their early annals. Pretending, as they do, to trace the foundation of their empire not only as far back as the time of the Deluge (of which, it is well worthy of remark, their traditions bear attestation), but even to a period long antecedent to it, it can scarcely be wondered at that a disposition should prevail to reject the whole as purely fictitious. There may be as much error in too great disbelief, however, as in too ready acceptance. The early annals of every nation are mingled up with much that is absurd, and obscured by the suggestions of ignorance and superstition. Nor are those Chinese historians, who trace the origin of their kingdom back through ninety millions of years before the Christian era, a whit more deserving of ridicule than the Romans themselves, who, with all their enlightenment, believed that the god
barbarous mythology took an immediate
share in sublunary matters. The only
ground for wonder, in regard to China, is,
modern writers, some even of our own count
have given in their adhesion to the fabulous
the native historians, and pretended to have
beyond doubt that the Chinese empire wa
more than 2000 years before the Christian
following may be given as an abstract of th
their veracious theories:—They suppose that
Mount Ararat, does not mean to particularis
vidual mountain, but merely the first land whi
itself upon the subsiding of the deluge, which
jecture to be the elevated parts of Asia: That
lowed the track of the large rivers of China
southward, as leading to a fertile and oper
and became the founder of the Chinese m
identifying him with the Fo-hee or Foo-she
history: That, becoming offended with the
his rebel offspring, he separated himself f
shortly before their presumptuous erectio
Tower of Babel; and, steering his course
after 200 years' peregrination, settled hims
of the northern provinces of China (2114 ye
Christ). Here, having settled his colony,
blished the religion, laws, and government,
had received from his antediluvian ancestor
in the 115th year of his reign, and 950th
(1999 years before Christ). He was succeede
nong or Zing-nung, who reigned 140 years,
death (1859 years before Christ) left the
Whang-tee or Hoang-tee, the inventor of Chi
metic and other arts, who reigned 100 year
his death left the crown to Shau-hau (1759
fore Christ).

But it were a mere waste of room to com
enumeration of this genealogical succession
Suffice it to say, that these theoretical histor
it, with painful accuracy, down to the reig
(1452 years before Christ), in the 67th year
monarchy happened the remarkable solstice
in the book of Joshua, and which is actually
the old Chinese annals, although without the
tion of any year. From this time downw
national records have undoubtedly some appe
veracity, being principally contained in the *S*
(or history) written by Confucius, who lived
years before the birth of Christ. Mr Barrow,
researches the present age is chiefly indebte
information most deserving of belief respe
singular nation, suggests a much more mod
rational supposition, of which the following is
stance:—He observes, that although the Chi
be admitted to have been among the first
the world, after the Flood, yet they do not
have made such progress in arts and learnin
Chaldeans or Assyrians; that it is only from
of Confucius that they seem to have advanced
sation; that previous to his time, the cou
divided into a number of petty kingdoms, und
rate chiefs, with a recital of whose reciprocal
struggles for superiority the Chinese annals a
filled; that their historical records are su
abundant and complete during the last 2000 y
the transactions of each reign fully detailed
interruption, down to the present time; a
during this time, the empire of China has
disturbed by foreign wars or intestine commoti
any other portion of the world of which we po
accounts.

Even from this view of the subject very grea
tions must be made. We are, however, com
walk according to our lights, and to offer the
summary of the Chinese dynasties, from th
when their chronicles begin to assume an air
bility:—

From the reign of Yau (mentioned above)
final succession of the present royal family of

· Tai-tsin, in 1644 (A. D.), the Chinese annals enume-
ıte twenty-two imperial dynasties. Three royal fami-
s are mentioned as having possessed the throne from
'67 till 258 before Christ—Kia, Shang, and Chew.
bout the latter year appeared a Chinese hero, Chi-
ang-ti, who overran the empire, extirpating all the
tty chiefs and rulers, and uniting the whole of China.
e also built the great Tartar or Mongolian wall, and
igned until the year 207 before Christ. This prince
s the first of the present family of Tai-tsin, who of
urse are justly proud of their great claims to anti-
uity.

The empire was, however, again dismembered, after
a death, under his son Ul-shi, but was re-united, ten
ars later, by Lieu-pang. He adopted the new name
Hang, and founded the dynasty of Hang. The
inces of this dynasty extended their conquests consi-
rably to the west, and took part in the affairs of
entral Asia. The religion of Tao-tse prevailed during
eir ascendancy; and in the same period Judaism was
troduced into China. In the course of time, the
inces degenerated, and, under Hien-ti, China was
vided into three kingdoms (220), which were again
ited by Wu-ti (280). Whilst the whole aspect of
urope was changed by the general migration of
ations, two empires were formed in China, with the
tinction of the dynasty of Tsin—one in the north
36), and the other in the south (420). After this,
hina was torn by internal commotions, and almost
ery province had a separate ruler, when, in 990, the
ople elected the able Shao-Quang-Yu emperor. He
s the founder of the dynasty Sing, or Song, which
igned till 1279. His immediate successors resembled
m, yet the country suffered considerably by the
vastations of the Tartars. Under Yin-tsong (1012),
e Chinese were forced to pay tribute to the Tartar
eao-tsang. Whey-tsong overthrew the empire of
eao-tsang (1101); but the Tartars possessed them-
lves of the whole of the north of China (Pe-cheli),
125. Kaot-song II. was their tributary, and reigned
er the southern provinces only. Under the emperor
ing-tsong, the Chinese formed an alliance with Genghis-
han, and the Niu-cheng submitted to this great con-
eror (1181). But the Mongols themselves turned
eir arms against China, and Kublai-Khan subjected
em, after the death of the last emperor, Ti-ping
260). Under the Tang dynasty, arts and sciences
ourished in China; several of the emperors them-
lves were learned men. The Chinese authors call the
Mongolian dynasty of emperors *Yuen* (from 1279 till
68), and Kublai-Khan is by them called *Shi-tsu*. This
as the first time that the whole of China was subjected
foreign princes. But the conquerors conformed
emselves entirely to the Chinese customs, and left
e laws, manners, and religion of the country un-
anged. Most of the emperors of this line were able
inces. But after the death of Timur-Khan, or Tsing-
ng (Tamerlane), 1307, and still more after that of
ou-Timur-Khan, or Tai-ting (1318), divisions in the
erial family frequently occasioned internal wars,
ch weakened the strength of the Mongols. The
ese Chu took up arms against the voluptuous
ka-mur-Khan or Shunti, and the Mongolian grandees
me divided among themselves. Toka-mur-Khan
d into Mongolia (1368), where he died (1379). His
n Bisurdar fixed his residence in the ancient Mon-
lian capital Karakorum, and was the founder of the
pire of the Kalkas, or northern Yuen. This state
not remain long united; but, after the death of
oz-Timur (1460), each horde, under its own khan,
came independent; in consequence of which, they
re, with few exceptions, constantly kept in subjec-
n to China after this period. Chu, afterwards called
-tsoo IV., a private individual, but worthy of the
rone, delivered his country from the foreign yoke,
d founded the dynasty of Ming (1368 till 1644),
hich gave the empire sixteen sovereigns, most of
em were men of merit. On the frontiers of the
pire, the remains of the Niudshee Tartars, now
called Mantchoos, still existed. The emperor Shin-tsong II. gave them lands in the province of Leao-tong; and when an attempt was made soon after to expel them, they resisted successfully, under their prince Tai-tsu, and obtained possession of Leao-tong, upon which their chief assumed the title of emperor. He continued the war during the reigns of the Chinese emperors Huan-tsong and Hi-tsong, until his death. His son Ta-tsong succeeded him, and Hoai-tsong, a good but weak prince, was the successor of Hi-tsong on the throne of China. On the death of Ta-tsong, the Tartars did not appoint any one to succeed him, and discontinued the war. But in China, Li-tching excited an insurrection, during which Hong-Puan put an end to his life (1644). Li-tching's opponents called in the Mantchoos to their assistance. They got possession of Pekin, and of the whole empire, over which they still reign. Under Shum-chi, a child of six years old, the conquest of China was completed (1646–47), and the present dynasty of Tsing was finally established. He was succeeded, in 1662, by his son Kang-hi, who subdued the khan of the Mongols, took Formosa, and made several other additions to his empire. During the reign of this prince, the Christian religion was tolerated, but his son Yong-ching prohibited it in 1724. The son of the latter, Kien-Lung, continued the persecution against the Christians (1746–73). He conquered Cashgar, Yarkand, the greatest part of Songaria, the north-eastern part of Thibet and Lassa, the empires of Miao-tse and Siao-Kin-tshuen, and extended his territories to Hindostan and Bucharia. He peopled the Calmuck country, which the expulsion of the Songarians had rendered almost a desert, with the fugitive Torgots and Songarians from Russia. In 1768, he was totally defeated by the Burmese of Ava: nevertheless, the Chinese took possession of a town in Ava in 1770, and returned to their country with the loss of half their army. They were more successful against the Miao-tse (mountaineers). Towards the end of his reign, his minister, favourite, and son-in-law, Ho-Tching-tou, abused his influence over him. Kien-Lung was succeeded, in 1799, by his 15th son, Kia-King. His reign was frequently disturbed by internal commotions. The Catholics, whom he favoured, have lost most of their privileges by their inconsiderate zeal; and at Pekin, the preaching of the Christian religion has been strictly prohibited. Kia-King was succeeded, in 1820, by his second son, Tara-Kwang, whom the Russians call *Daoguan*.

Such is a brief summary of the historical annals of this singular people. Throughout their chronicles occur many periods which are completely blank, and these chasms have been filled up, as usual, with gross fables, which throw an air of doubt over the whole; but it is worthy of remark, that many of the leading facts recorded in their more veritable histories, have been confirmed by contemporary travellers and historians of other nations.

On the whole, however, it appears, that, instead of having existed as a great and united nation from a period of 3000 years before Christ, as the natives pretend, China was not formed into one state until between 200 and 300 years before Christ. Since the establishment of the Mogul dynasty, the empire has not been again divided, but has experienced two great revolutions, at the accession of the Chinese dynasty of Ming, and the re-accession of the Mantchoo Tartar dynasty (Tsing) in 1644; and has scarcely in any reign been free from revolts, wars, and domestic seditions. Instead, therefore, of having a right to be regarded as a privileged country, governed from time immemorial by the same constitution, exempt from foreign conquest and intestine commotions, the only peculiarity it possesses, distinct from the other empires which have been swept from the earth, is—that owing perhaps to its peninsular situation, at the extremity of the habitable world, and its consequent exemptions from the destructive sweep of those conquering nations who supplanted those whom they overthrew, it has preserved its usages and man-

ners in a great measure unaltered, amid the many internal revolutions it has undergone. Still, the fact of this, the greatest mass of population which was ever united under one government, being kept together in one bond of union for a period of time far exceeding that at which the earliest European nation may be said to commence, presents a moral phenomenon of the greatest interest, and seems altogether inexplicable by any of the usual principles which are supposed to bind society together. That it has neither been owing to the nature of the government, nor the virtue of the princes, nor the morality and peaceable disposition of the people, is certain; and we can only conjecture that the system of strict exclusion from all communication with foreign nations, and the national habit of appealing to ancient usage as the universal rule of conduct in all matters of life, have served to preserve their primitive habits and ideas in a great measure unchanged, and left unstimulated those energies invariably called into action by the free intercourse of mankind.

GOVERNMENT.

The government of China is not so much what is usually understood by an "absolute monarchy," as a specimen of what we learn from history to have been the social arrangement of a patriarchal family. The emperor, like the "head of a house" in those times, is perfectly unlimited in his power over all under him. He can dispose of the lives of his subjects at pleasure; can make or abrogate whatever laws he chooses; all offices and emoluments emanate from him alone; in short, he is equally the source of all power, honour, and mercy in the state. He can even appoint his own successor to the throne, either from his own family, or whatever class of his subjects he pleases. One of the leading principles in the Chinese constitution is to place as great a distance as possible between this universal autocrat and his subjects, and to hold him up as a demigod, a sort of *dragoman* betwixt heaven and mortals, alternately communicating the decrees of the one and the petitions of the other. He is altogether exalted above the common gross sphere of humanity. He is styled the "Holy Son of Heaven, sole guardian of the earth, and father and mother of his people." In fact, he is *believed* to be of heavenly origin; and this superstitious notion appeared sufficiently obvious by the obstacles opposed to the succession of the present Mantchoo dynasty, on account of their family not being able to trace its descent through more than eight generations. The new monarch, aware of the danger of this stigma to the stability of his throne, caused his genealogy to be drawn out and published, wherein it was given out that the daughter of heaven, descending on the borders of the lake Poulkouri, at the foot of the White Mountain, and eating some red fruit, conceived and bore a son, partaking of her nature, and endowed with wisdom, strength, and beauty; that the people of that nation chose him for their sovereign, and that from him was descended the present Son of Heaven, who filled the throne of China. This explanation at once satisfied all the scruples of his celestial subjects. Offerings are made to his person and throne, and he is worshipped by prostration, not merely in his presence, but in places where he is *supposed to be present*—as our sailors lift their hats on coming upon the quarterdeck of a man-of-war. When Lord Amherst, in his ill-starred mission to Pekin in 1816, stopped at one of the stages towards that capital, a repast was found prepared by orders of the emperor, and he and his suite were ordered to prostrate themselves nine times before the *table*, as if the descendant of the red fruit of Lake Poulkouri had been personally present. It is, of course, only in keeping with such superstitious notions, that the emperor should be reckoned not only the sovereign of China, but of all *the world besides*, the other royal personages being *merely his vassals*. "Heaven has not two sons; earth *has not two kings*; a family has not two masters; sove*reign power has not* two directors: only one God and *one emperor.*" Such were the precepts of the learned Confucius, 500 years before Christ; and such doctrine of the Chinese at this hour.

This irresponsible autocrat bears two distinct racters: first, that of high priest; and, secon of the sovereign of the empire, or "father and of the people." In the first character, he is so ator with Heaven for the sins of the nation; officiator at all solemn rites and sacrifices for p ing the favour of God. He has thus the exclusi of all the blessings the people enjoy—such as crops, favourable weather, &c.; and although o of public calamity, storms, inundations, and su ters, are also laid to his charge, yet such is fatuation of the people, that they forgive his consideration of the proof thus afforded of the of Heaven to his conduct! But care is always present his character in the most amiable light to his subjects, who only hear of him as pract the Utopian virtues of his station—remitting t punishments, protecting virtue, punishing opp relieving the poor. So much for the head of cutive. What may be called the administrative ment, consists of the emperor's council and t public tribunals. The council is composed ministers of state, taken from the first order darins, and presidents of the supreme tribunal never assembled except upon occasions of extre lic importance; every thing being in general by an inner council, where the emperor sits in p There are six superior tribunals at Pekin. T named Lü-poo, watches over the training of rins, or persons to fill official situations, as well their conduct after being appointed to office; their proceedings and character to the emper in short, has them entirely under its surv The second tribunal, called Ho-poo, may be de the court of finance, where all the revenues empire, the royal treasures and domains, an branch of public expenditure, are managed. Th tribunal, Lee-poo, or the court of ceremonies, tends the observance of ancient customs and r ceremonies; examines the public schools, and the progress of the sciences; receives foreign emb (a great tax on their time!) and regulates all of etiquette about the court. The fourth tribuna poo, is something akin to our war-office, in hav management of all the military concerns of the Fifth, Hong-poo is the police department, di every thing relating to the detection and punish crimes. The sixth tribunal, Kong-poo, is the t of public works, having charge of the palaces, buildings, canals, mines, manufactories, &c. A tribunals have under them a great number of s nate tribunals scattered throughout the empire, vient to their various objects of institution. Eac six supreme tribunals has two presidents, one o must be a Tartar by birth, and the other a C They have, also, twenty-four assessors, who a Chinese, half Tartars.

There is, also, another tribunal, the nature of sufficiently demonstrates of itself the grand p upon which the Chinese government is based—t of making every thing depend upon the emper is a board of *censors*, who send an inspector to over the proceedings of each of the tribunals—b supreme and subordinate. These functionaries part in the proceedings of the tribunals, but me and attend to all the proceedings, which they r their principals, and these again to the emperor. agents are, in short, his spies; and by them he in governs his empire. The mandarins are change one situation to another every three years, to p their acquiring too much influence with the pe which times they are obliged to appear regul court—to resign the seals of office, we suppose, the ground, upon entering on a new one.

The beautifully complicated machinery of g ment just described, might be supposed, if ye regulated, well adapted for accomplishing its

, and destroy all genuine sentiment amongst them. the beggar upwards to the sovereign, each indi- is the slave of him immediately above himself; what is worse, all are aware of the hypocrisy of other, and there are no other bonds to hold society er save the chains of tyranny.

LAWS.

Laws of this singular nation may be described as of the bamboo, the cord, and the scimitar. "This nation," says Mr Barrow, "may be aptly enough ared to a great school, of which the magistrates he masters and the people the scholars. The on is the ferula, and care is taken that the child not be spoiled for sparing the rod. The bamboo, ver, is not used merely as an instrument for flog- he people. In the fundamental laws of the empire, ns the scale by which all punishments are sup- to be proportioned to the crimes committed, and are carefully dealt out by weight and measure. hment, as an example to deter others from the ission of crimes, would seem, indeed, to be less bject of Chinese legislation, than that of satisfying laims of rigid justice—to wipe off a certain degree ime by the infliction of a proportionate degree of ing."

e laws are embraced in a code called the Lan-lee, has generally undergone some modifications each new dynasty, but has continued fundamen- the same from time immemorial. It is one of the s of the mandarins to instruct the people in the sions of these laws, and they are likewise promul- in all the schools and public seminaries. The of the present family, called the Tai-tsin Lan-lee, sts of six great heads, to correspond to the func- of the six supreme tribunals, and embraces an ne of the whole system of government. Our rs would not, we believe, thank us for an exposi- f this institute of Asiatic jurisprudence; but the division, relative to crimes and punishments, ins matter sufficiently curious and interesting. son—which, besides the crime of rebellion, com- nds nine other species of offence, amongst which arricide, impiety, and desertion to a foreign power nvariably punished with death, in the former case the most lingering tortures. But it is not merely the criminal himself that the penalty for treason

All the male relations of such persons are indis- nately beheaded, the females sold into slavery, and eir connexions relentlessly put to death. And it is lid the vengeance of the law always terminate here; too frequently happens that whole villages, nay, times entire districts, are indiscriminately slaugh- for the crime of one individual! To intrude into the f the imperial retinue while the emperor is travel- subjects the offender to death. One of the most ordinary decrees is, that if the emperor's physician scovered compounding any medicine in a manner anctioned by established usage, he is punished with blows. If any dirt is found amongst his majesty's the cook receives eighty blows; and if he mixes unusual ingredient or sauce, which his majesty's e does not agree with, he receives 100 blows, and mpelled to swallow the article himself! All cases eliberate murder are punishable by death; and , with the most lingering tortures, is denounced st parricides. The penalty of death is also awarded st a slave who shall strike his master; a son who strike his father or mother; a grandson who shall e his grandfather or grandmother; a wife who shall e her husband's father, mother, grandfather, or dmother. But if a father kill a son, grandson, or , even designedly, the punishment is no more than blows of the bamboo, and a year's imprisonment. this lenient punishment is generally remitted for e, as the law presumes the cause of the act to be isobedience of the child, which is held as a crime e deepest dye, as affecting the principle of the whol em of government. The jealousy of the Chine

law on this important point is further illustrated by the following decree—"That a child or grandchild, who is guilty of addressing abusive language to his or her father or mother, paternal grandfather or grandmother; a *wife* who is guilty of the same to her husband's father or mother, paternal grandfather or grandmother—shall in every case *suffer death by being strangled!*"

There are five degrees of punishment for offenders:—The first is inflicted by the lesser bamboo,* and is said merely to be in the way of reproof and admonition. The correction extends from four to twenty blows. The second degree extends from twenty to forty of the larger bamboo. The third is temporary banishment to the distance of 150 miles, extending from one to three years. The fourth degree is perpetual banishment, with one hundred blows of the bamboo. The fifth and ultimate punishment is death, either by strangulation or decollation. There are also various kinds of torture to extort confession and evidence. The punishment by the bamboo, however, is, in the case of offences committed by the officers of government, commuted to fine or degradation, and, under peculiar circumstances, the benefit of commutation by fine is extended also to private individuals. In fact, there is a regular scale of charges for those not legally excluded from the degradation of flogging, of which all who are rich enough may avail themselves. The motive of this regulation is evidently to fill the coffers of the royal treasury.

REVENUES.

No correct estimate, for want of the necessary data, has ever been ascertained of the actual amount of the revenues of this immense empire, and the most different statements have been put forth on the subject by various writers and travellers. The Chinese themselves, of course, attempt to impress foreigners with a most exaggerated idea of its magnitude. A Chinese minister represented it to Lord Macartney as amounting to a sum exceeding sixty millions sterling, of which, after defraying all the civil and military expenses, about twelve millions were supposed to remain for the emperor's private support. Mr Barrow reckons "that fifty millions, in an economical government like this, where the officers and magistrates are so shamefully paid that they could not live without robbing the people, may be considered as an ample revenue for all the necessities of the state." Some late writers have reduced the estimate as low as twelve millions; but such a calculation is evidently absurd. Perhaps the nearest to the truth is that of the intelligent M. de Guignes, who accompanied the Dutch embassy in 1794. He drew up a minute summary of each individual tax and branch of expenditure, and their amount, and the result was as follows:—

Revenues, - - -	£31,555,554
Expenditure, - - -	22,222,221
Surplus,	£9,333,333

—the surplus, after the emperor takes what he immediately requires, being deposited in the public treasury. If this calculation be correct, it is evident that enormous sums must thus sometimes be accumulated. Mr Barrow, it is true, says, "that the immense treasures said to have been amassed by the reigning dynasty, exist only in the imagination of the Chinese." But he seems to have forgotten what he himself states in another place, where, speaking of the various means adopted to preserve the emperor's popularity, he tells us that the sovereign sometimes remits a whole year's taxes to his people—a proceeding which could not easily be put in practice with an empty exchequer. The emperor has also private domains, the revenue of which was estimated by M. de Guignes at upwards of four millions.

The revenue is raised from a land-tax, amounting to about a tenth of its produce, one-half of which is paid in money, and the other half in kind. There is, besides this, a tax on salt, coals, and manufactures; and a capitation-tax upon merchants, artisans, &c., who are held lowest in the scale of society. It is a curious fact, that the regulations for collecting the duties on manufactures, and preventing smuggling, resemble exactly the British system of permits, excise-officers, licenses, &c. In addition to these revenues is the large amount raised by the duties on foreign shipping and merchandise, of which we will have further to speak when we come to treat of the trade of China.

ROYAL FAMILY—COURT DRESS AND CEREMONIALS.

As may be imagined, the emperor is domiciliated in a style suited to his immense wealth, high rank, and pretensions to unlimited sway. His train of courtiers, officers of state, and other attendants, when he appears in public, which is exceedingly seldom, is inconceivably numerous; and being all apparelled in gorgeous silks and satins of the brightest dyes, garnished with gold and silver, their appearance is inexpressibly magnificent. But it is only while going through this public exhibition that all this show of wealth and magnificence has any reality. When released from duty, they return to their mean and solitary cells in the outskirts of the palace, where they devour their rice out of wooden bowls with their chop-sticks, and then lie down on their mats on the uncovered floor, to slumber away the hours till their services are again required; for to enter into conversation with his fellow-slaves, would, as being so strange a departure from the national taciturnity, subject the parties to the suspicion of conspiracy.

The emperor has three classes of wives. The first consists of one who has the rank of empress; the second, of two queens and their attendants; and the third, of six queens and their attendants. The emperor's wives and women are doomed to reside for ever within the walls of the palace, and are, after his death, imprisoned for life in a prison called the "Palace of Chastity."

The princes of the blood who are descended in a direct line from the reigning family, have their names and dates of birth registered in a yellow book, and have the privilege of wearing a yellow girdle; but those who are only of collateral descent, have their names enrolled in a red book, and wear a red girdle. So inimical is the spirit of the government, however, to a multitudinous nobility, that even the princes of the blood beyond the third generation, unless they have talents and learning to recommend them to some honourable employment to which rank is attached, gradually merge into the common mass. The princes have the privilege of being tried only by their peers, and may procure exemption from any corporal punishment by a fine. The persons of those who wear the yellow girdle are held so sacred, that any one insulting them incurs death. Those who hold no office, only receive a salary equal to the pay of a common soldier in the Tartar bands, and receive 100 taels (about 30 guineas sterling) at their marriage. The emperor and his children wear robes of satin of a bright yellow colour, while all the other branches of the royal family, like the mandarins, wear robes of a violet colour. The emperor, his sons, and those of the first rank, are also distinguished by figures of dragons with five claws embroidered on their vestments; princes of the second rank have dragons with four claws: those of the third rank, as well as the mandarins, have, instead of dragons, serpents with four claws. The *button of ceremony* on the headdress of the emperor consists of three dragons of gold, placed one above the other, encircled and studded with pearls. His upper robe has four circles embroidered with dragons. His necklace, which in his case alone is composed of pearls, consists of 112 pearls, and other ornaments of rubies, sapphires, and amber. His girdle is of a bright yel-

* This instrument, which makes so conspicuous a figure in the Chinese code, is of two sizes: the larger is five feet eight inches *long, two and three-fourth* inches broad, and two inches thick, *weighing two and two-third* pounds; the smaller is the same *length, two inches broad, one* and one-fifth thick, and weighs one *and five-sixths of a* pound. The infliction is applied in open court, *immediately upon sentence* being passed.

The population of China, under the emperor himself
l his family, may be divided into eight distinct classes.
d one of the most striking circumstances in the
ial system of this great despotism is, the want of that
ich has almost universally been reckoned indispens-
le to the stability of a monarchy—*a nobility*. With
exception of the princes of the blood, whose per-
s are in some degree held sacred, there is no rank
what is derived from the holding of some office in
state. But although those thus favoured are, by
rtesy, esteemed noble, and even some families are,
the emperor's favour (such as the descendants of
nfucius), allowed to retain a title of honour, they
ive no power, privilege, or emolument therefrom.
e sons of the highest mandarins derive no dignity or
vantage from the rank of their fathers. As the pos-
sions of a parent, too, are all equally divided amongst
sons, the riches of the greatest families diminish in
portion to the number of heirs; and if these are no
y distinguished by talent, they soon sink back into
common mass of the people.

The great body of the people may be divided into the
lowing classes:—The MANDARINS, the MILITARY, the
ERATI, the BONZES (or priests), the HUSBANDMEN, who
the most favoured class in the state, the ARTISANS
d the MERCHANTS, who are the *least* respected, *espe-
lly those who traffic with foreign nations!* It is one
the most curious features of this singular government,
t, being so essentially despotic in itself, both in prin-
le and practice, it possesses one feature generally
kened the main principle of a democracy—namely,
t *the highest honours and offices in the state are alike
n to all classes of the people*. The meanest origin
no bar, and the proudest rank is no recommendation
the individual. This system no doubt soothes the
blic mind, and induces the people to bear with
ater patience that insolence of office and stretch of
wer which they themselves have the prospect of ex-
rising in turn. The result, however, is exactly in the
erse ratio to the plausibility of the system. "Where
offices of state," says Mr Barrow, "are open to the
ry lowest of the people, when possessed of the re-
isite qualifications, the candidates for employment
come so numerous, that every trifling fault is laid
ld of to create a vacancy; and these frequent re-
vals and degradations fall in precisely with the system
government, which is to break down all connexion
tween the officers and the people, and to turn the
spect and veneration of the latter exclusively to the
vereign." It is found, that the more mean the ori-
nal condition of a mandarin has been, the more op-
essive and extortionate is his conduct to those under
m, not only with the view of making his origin be for-
tten in his present elevation, but, knowing the inse-
rity of his situation, of making the most of it while it
in his power. The people, however, submit patiently
his exactions, assured that his dismissal (of which
ey are certain) will open the way for one of them-
lves to enjoy the same opportunities of robbery and
pression.

In accordance with the national system, however,
e office of mandarin, to which all ranks eagerly as-
re, is almost wholly engrossed by individuals selected
om the three humblest classes—the husbandmen, the
tisans, and the merchants. Those who have acquired
ealth, by whatever means, generally enter into some
these occupations to render them more eligible for
e office, in order that, by attaining it, they may enjoy
eir possessions in more security. Others purchase the
fice with their whole fortune, secure of finding the
eans of recruiting their finances during their three
ars' administration.

The mandarins consist of two classes, the civil and the
ilitary. The former, however, are the chief officers
ho govern the empire, although they are placed under
uch restrictions as to prevent their ever becoming da
gerous to the emperor. They cannot marry in the

vince or city they govern, nor hold office in a province within fifty leagues of that where they were born, until they are sixty years old; with many other despotic regulations of the same nature. A mandarin has unlimited power in his district, but his conduct is watched by those above him, as it is the policy of the Chinese government to make every department responsible for the one immediately inferior to it. Notwithstanding this surveillance, however, and although their salary is barely sufficient for simple maintenance, it is regarded as a phenomenon by the Chinese to see a mandarin leave office without amassing great riches. Their means of accomplishing this we have already explained under the head of Government. Notwithstanding their infamous exactions, the people observe towards them the greatest reverence. They are saluted with the title of "Great Lord," and every one bends the knee while addressing them. The two chief classes of mandarins are divided into nine different orders, who are all minutely distinguished by particular parts of their dress. The most marked, however, is the button in the bonnet, which, among those of the first order, consists of a red ruby; others of a meaner order have a rock crystal; and the most inferior, one of gold. The number of civil and military mandarins is calculated at between 20,000 and 30,000.

The *literati* form the most distinguished part of the Chinese nation, as it is from amongst these that the individuals necessary for discharging all the higher duties in the state are recruited. To ensure the adequate accomplishment of these learned statesmen, there is, as before stated (under the head of Government), a board of censors, named *Lü-poo*, to direct their studies, and examine into the progress of their erudition; and government has fixed for every city of the first, second, and third class, the number of literati allowed to qualify themselves annually in each, by taking out a diploma, corresponding to the degree of Bachelor of Arts in Britain. There are, then, in China, upwards of 24,700 individuals annually added to the qualified literati; and it is therefore conjectured, that there are never less than 495,000 of this body. These are all exempt from taxes of every description; and as soon as they have taken out their degrees, their names are enrolled in the lists of the *Lü-poo*, who choose from amongst them the higher orders of mandarins.

It is, however, in productive labour that perhaps two-thirds of the Chinese are employed; the remaining third, amounting, after deducting the civil and military officers, students, literati, &c., to about ten millions, being engaged in trading and manufactures. It is the great maxim of the Chinese government, that agriculture is the true source of national prosperity and wealth; and they have in every age honoured and protected the cultivators of the soil. This class, indeed, may be considered much the happiest and most independent of the nation; for although they pay to the amount of a tenth annually to the emperor, they have neither priesthood nor poor to support—unless the poor of their own families, whom all classes are bound to provide for. The monarch is the universal proprietor of the soil, and the tithe exacted from it is the whole rent paid by the farmer. But though the cultivator is thus in a manner a tenant at will, he is never disturbed in his possession so long as he continues to pay his land-tax, and has the power of letting out any part, or the whole, if he pleases, to another. As there are no public funds in which to vest capital, and commercial speculations are reckoned degrading, all classes are eager to lay out their capital in land. It is for this reason that even the princes and nobility vie with each other in countenancing agriculture. Yet, notwithstanding all this encouragement, the amount of land cultivated is trifling in comparison to the extent of the empire. By a report made to Kien-long in 1745, it appeared that there were only about 6,000,000 *of acres under cultivation*, out of the 640,000,000 *calculated to be capable of* tillage. From the want of *enterprise, but still more* from the want of skill and *suitable implements*, immense tracts of land are allowed to lie waste; and it is estimated that a fourth of the whole country consists of lakes and swamps, most of which are capable of being drained. It will easily be seen how inadequate the produce of the soil is to ensure a regular supply of food to the inhabitants, in case of scarcity, occasioned by long droughts, which frequently occur; and when it is considered that there is no foreign supply of grain to make up for deficiencies, little wonder need be expressed at the terrific famines which often afflict the nation. To provide against these scarcities, a year's produce of the land is always kept stored up in public granaries; but this provision is never found sufficient to prevent the frequent recurrence of the most dreadful scenes of starvation.

We are somewhat puzzled what to say regarding the amount of the population of China; for although all accounts agree that it is something enormous, there is a difference of millions between the statements proceeding from what may be termed the most authentic sources known. The mandarins attendant on Lord Macartney, in the year 1793, gave out the population at 333 millions; and by a census taken in 1813, by order of the Chinese government, this enormous mass is swelled up to 367,821,647, which gives about 263 to the square mile. According to a statement in a Chinese official document which is quoted with approbation by Dr Morrison, the population at present is 352,866,81[illegible]. Of the truth of this statement nothing can be said, as considering the small extent of cultivated land in the empire, it appears to be greatly exaggerated. The supposition is, that it not only includes China Proper but all the surrounding states, which are either dependant upon, or pay tribute to the empire. According to Thom, the population is 181,780,163, which he divides into the following religious sects:—

Followers of Confucius, Laou-tsze, and Taou,	159,220,163
Worshippers of Lama,	18,000,000
Mahommedans,	1,600,000
Roman Catholics,	88,000
Jews,	50,000
Boodhists and others,	2,830,000
	181,788,163

This table is perhaps as near an approximation to the truth as can be made, although the calculation is thought by some to be too high for the extent of cultivated ground. According to a parliamentary paper published in 1830, the population of China Proper, exclusive of Tartary and the other dependencies, is 141,470,[illegible] souls. In the German Statistical Almanac, published at Weimar in 1838, the population of China Proper is estimated at 148,000,000. From the same authority we learn that the army in 1835 was 1,250,000 strong, comprehending 830,000 infantry, and 420,000 cavalry; and the naval force is calculated at 32,440 men.

PRODUCTIONS—AGRICULTURE—TEA CROP.

The staple productions of China are rice, tea, silk, cotton, sugar, salt, porcelain, tin, lead, musk, rhubarb, quicksilver, saltpetre, wines, fruits, and various manufactures.

Rice is the great staple article of food; and so much is its importance regarded, that a high festival is held at the commencement of each seedtime. The emperor performs in person, and prepares himself for the solemn occasion by three days' fast and prayer. He then goes forth in great pomp, takes the plough in his own hands, opens a furrow, and throws in the first seed of the season. The same is done in every part of the empire on the same day, by the viceroys and governors. The grain reaped from this seed is preserved in granaries and reserved for sacrifices. The cultivation of this grain, of which there are two crops annually, requires little or no labour; water supplies every purpose, and for the most part this element is abundant in every part of the empire. The growers display great ingenuity in their various contrivances for raising the water from the rivers, by means of wheels, [illegible]

e black tea is grown in the maritime province of
en, with the exception of about one-third of the
, which is produced in the north-east corner of
n province, in a district called Wo-ping. Green
all grown in the maritime provinces of Kiuguan,
g-si, and Che-Kiang, but chiefly in the two former.
of the buds of the plant in Fo-kien are picked in
rly part of the spring, before they have burst,
small portion of these is mixed with the best
ds of congou, to give them a flavour. Pekoe is
brought to Canton unmixed with other leaves.
the beginning of April, the leaves are stripped off
lant; a new crop is then thrown out, and picked
six weeks afterwards, and a third crop about the
f May: the two first pickings are the best, and
y equal in quality. The third crop of leaves
s tea of little strength and inferior flavour: hence
est crops are composed wholly of the choice leaves
e two first gatherings, with a small sprinkling of
uds or pekoe. The inferior crops contain a larger
of the third pickings, and none of the pekoe.
black tea in Fo-kien is cultivated largely by cot-
s in small plots of ground or gardens. The leaves
icked by the family, and immediately sold to per-
whose business it is to collect quantities of them,
manufacture them in parts, that is, expose them to
ried by the wind under the shade, and afterwards
further dried in a heated warehouse. The tea-
hants and the agents of the Hong merchants exam
e tea districts, and purchase quantities of the dried
s of the first, second, and third gatherings, discri-
ting the leaves of young and old plants, and those
n in well-known favourable spots. They then
plete the drying or roasting process, and employ
en and children to select the hard, the best leaves,
more or less discrimination, according to the
t of making very fine, middling, or common tea.
green tea is less highly dried than the black; and
Barrow supposes that it is from the former thus
ning much of its natural juices, that its nervous
erties (generally ascribed to its being dried in
er vessels) are to be imputed. The green tea is
lly pressed into chests while hot, to give it a finer
ur. The tea is made into parcels of from 100 to
hests each, with a distinctive name to each parcel,
conformity of quality, where the tea-merchant acts
stly; hence those parcels of tea, which, under
in Chinese names, have proved, in a series of years,
xcellent quality and similar characters, and which
greatly sought after at the London sales, are not
roduce of any particular farm, but owe their cha-
r to the skill and good faith with which the tea-
hant or the Hong merchant's agent have executed
commissions in selecting only superior parcels of
a in the markets of Woo-y-shan. Like the black
the different classes are formed by selecting the
r from the inferior leaves after they have been
; the light leaves separated by a winnowing ma-
e from the heavier, the latter of which constitute
gunpowder tea; the lighter are of inferior quality,
only used by the common people. The blooming
arance of hyson, gunpowder, &c., is said to arise
the effects of carefully roasting the leaves in iron
s placed over a fire, and by rubbing them against
sides of the vessel; in this process, with the green
, much skill is requisite, and there is a class of per-
hired by some of the tea-merchants to superintend
r respective manufactories. The bohea tea is com-
d partly of the lower grades of the Woo-y-shan tea,
h has been left unsold after the departure of the
ships of the season, and partly of the tea grown in
district of Canton called Wo-ping.
he tea-chests undergo severe scrutiny in Canton,
iously to being purchased; and if, when finally
mined at the period of their shipment, they are
d superior to the quality which has been attached
hem, their price is raised; if inferior, they are
cted, or their price lowered. The scientific mode
roving the finer teas is to put a small quantity into

a cup; pour on it pure spring water at full boiling heat; place the saucer above the cup, filling it also with boiling water to increase the heat: after a sufficient time has elapsed for the leaves to unfold themselves, to examine the appearance, flavour, but particularly the *colour* of the infusion. The latter quality is of course only known to the initiated.

Tea is the universal beverage of China. It is drunk at all meals, and is almost the only liquor used at feasts, and while visiting each other. But it is a general rule amongst them never to drink tea immediately after a long fast, it being apt to affect the nerves, and create giddiness. The tea-shrub is cultivated only in China and Japan, and is supposed to be indigenous to one or both of these countries. All attempts to introduce it into Europe have hitherto failed.

The quantity of tea annually plucked in China, it is impossible to calculate, unless we also knew the quantity consumed by the natives. About 54,000,000 of lbs. are annually exported from Canton to all parts of the globe; and it is a remarkable fact, that of this quantity Great Britain and Ireland alone consume nearly 32,000,000 lbs.—being about 10,000,000 lbs. more than all the nations of the civilised world put together!

As substitutes for tea, the Chinese use a species of moss common to the mountains of Shan-tung; an infusion of different sorts of ferns, and the leaves of the common cammelia.

A plant called the oil-bearing tea, is much cultivated for its seeds, from which an oil is expressed, in very general use in the domestic economy of China. The seeds are ground to a coarse powder, boiled in bags, and then pressed, when the oil is yielded. There is also cultivated a tree of considerable height, called the tallow-tree, from the seeds of which a substance is prepared, having all the properties of animal tallow. A species of white cabbage is in very general use, and is considered to be to the Chinese what the potato is to the Irish. Fruits of every kind abound, but they are not considered good, except the orange, and a species called lee-tchee.

MANUFACTURES.

From the inveterate adherence of the Chinese to ancient customs and practices of every description, they have been left completely behind by almost every civilised nation in all useful mechanical arts, even those which originated with themselves. Every thing seems to have stood still in China but time. Nothing can be more illustrative of this fact than the case of the silk-manufacture, of which they were undoubtedly the inventors, and the knowledge of which, as their annals boast, they possessed 3000 years before Christ. The native reeler and weaver still continue to labour on by the same tardy process, and with the very same materials, as were used by their ancestors; while in England, where the manufacture was totally unknown until the fourteenth century of the Christian era, Sir Thomas Lombe, so far back as 1718, erected at Derby a machine driven by a water-wheel, by every revolution of which wheel 73,726 yards of organised silk-thread were thrown off, and amounting per day to 318,504,960 yards! At this day, the silks of China will not bear comparison with those of Lyons, Spitalfields, and Edinburgh; the first for light fabrics, the second for the more substantial, and the last for shawls. Again, in the article of porcelain (from the Portuguese *porcella*, a cup, they being the first who introduced it into Europe), which, until a very late period, continued to be the admiration of the world, we have been enabled, through the researches of Reaumur and other chemists, to compound earths matching that with which nature voluntarily furnishes the Chinese, and not only equal them in the fineness and durability of the ware, but infinitely excel them in elegance of manufacture. For nearly a century, the clumsy fabrics of the Chinese, with their daubs of blue paint, which formerly were the principal ornaments of the mansions of the wealthy, have been driven *out of the market by* the beautiful wares of Dresden, *Staffordshire, and Sèvres.*

The same remarks may be applied to all the other manufactures of China, the principal of which, besides the two above mentioned, are those of cloth, nankeen (or cotton), linen, paper, and ink. In whatever department of art the Chinese continue to maintain a superiority over, or equality with, the rest of the world, the cause is to be found in the bounty of nature, not their own ingenuity. Thus, the beautiful yellow which distinguishes the nankeen cloth, is a natural quality of the cotton grown in the province of Kiang-nan (of which Nankin is the capital), and is to be found in no other district of China. The Chinese still pertinaciously adhere to their ancient practice of fabricating their paper from the bark of the bamboo and koo-tchoo (by the latter of which names they term it), notwithstanding their being perfectly well aware of the superiority of that made from rags, and the infinitely greater cheapness and simplicity of the manufacture.

The Chinese ink is obtained from the soot produced by the smoke of pines and the oil in lamps, mixed with the isinglass of asses' skin and musk, to correct the odour of the oil. It is principally made in the province of Kiang-nan.

ARTS AND SCIENCES.

What we have said respecting the stationary condition of the manufactures, applies equally to the arts and sciences of China. The process of printing continues the same as when originally invented by themselves about 1700 years since. The characters are first written on paper, which is glued upon boards of hard wood, and the engraver carves the characters upon the wood, hollowing out the intermediate parts. When an impression is to be taken off, the printer lays on the ink with a brush, applies the sheet of paper, which he presses down with a softer brush than the other, and with a greater or less degree of pressure, according to the quantity of ink laid on. Such is the primitive mode of printing still persevered in throughout the interior of China, although moveable types are of course necessary in printing the Royal Gazette of Pekin, which is issued daily, and other documents.

One of the most singular features of Chinese genius is developed in their attempts at painting. They display extraordinary powers of minute imitation, and will copy with the utmost exactness the number of petals, thorns, spots, &c., of a flower, and the scales of a fish; but they are utterly unable to mix and soften their tints, and copy every defect as well as excellence in the object of their imitation. They have not the slightest idea of perspective, considering the diminished and faded appearance of distant objects as the consequence of a defect of vision; and they therefore insist upon placing every object in the foreground. When one of their ministers of state beheld a portrait of his Britannic majesty, he remarked that it was a pity it should have been spoiled by the dirt on the face—meaning the shading of the nose. When they draw a picture of the emperor, they consider it would be almost impious to represent him of the ordinary human proportions, and therefore make him twice as large as any of his attendants—the head particularly. But this self-conceited people consider themselves in this, as in every other art, pre-eminent over all other nations, and reject with disdain the remonstrances of European artists.

In sculpture, as in painting, the Chinese have no conception of order, attitude, or proportion; and there can be nothing more monstrously grotesque than the figures which *adorn* their temples, bridges, and tombs. It is affirmed, indeed, by recent travellers, that there is not a statue or column in the whole empire worth notice.

The Chinese music remains in that state of primitive simplicity in which it has been observed to exist in all barbarous nations. Dr Burney says, that "all the melodies of this nation have a strong analogy to the old Scottish tunes;" that "both resemble the songs of ancient Greece;" and that "the music of all three ought to be considered as *natural* music." Their gamut, like

ce of astronomy, for their proficiency in which
have hitherto enjoyed a great reputation. Their
pretensions in this department turn out to be
ded fully as much on superstition as scientific ob-
ation. So sensible are the Chinese monarchs of
fact, that for many generations the construction of
r vaunted Imperial Almanac has been intrusted to
ignors, the native astronomers only contributing
important department of fixing the lucky and un-
y days, days of festivals, &c. "The Chinese system,
stem it can be called," says Mr Barrow, "resembles
inely that which remains of the Hindoos, that both
t have been derived from the same source. The
le, or cycle of sixty years, by which their chrono-
is regulated—the period of 10,800 years observed
e Tae-tse, which is the sum of the first three Hindoo
, with their intermediate periods—the division of
odiac into twelve signs, and also into twenty-eight
tellations, or habitations of the moon, correspond-
with the twenty-eight Hindoo nacshatras—are so
y signs of a common origin; and both may perhaps
derived the remains of this science from some
d nation, more ancient than either; as the little
h both nations do possess appears to be the remains
er than the elements of the science." There is,
rtheless, a board of astronomers and mathemati-
s maintained at Pekin, which is, in fact, one of the
ial departments of government; and a committee
nually appointed with great ceremony to superin-
the compilation of the national calendar. It is
ous to see this ostentatious show of a love of learn-
kept up by a people who are still so ignorant as to
on that the firmament is a body encircling the
h, the latter of which is a solid fixed square, and
d which the sun revolves, as well as the moon;
all the stars are stuck into the sky at an equal dis-
e from the earth;—who gravely decide, by the state
he planetary system, the days proper for taking
icine, marrying a wife, setting out on a journey,
g the foundation of a house, &c. Their geogra-
al is on a par with their astronomical knowledge, as
be imagined from their supposing China to be the
dle region of the globe, and terming one mountain,
h is reckoned the centre of the empire, the "Navel
e Earth." The more educated are at this day well
ainted with the fallacy of such doctrines, but they
still propagated amongst the mass of the people, as
ould be equally impolitic and dangerous to expose
delusions which have obtained credence amongst
n from time immemorial, and the gross ignorance
heir idolised sages. The fact is, that the pretended
wledge of the literati, and ostentatious patronage of
ning by the government, is a mere state-trick, for
purpose of exciting the veneration of the ignorant
titude.

f natural philosophy, or chemistry, the Chinese
w literally nothing, except from a practical acquaint-
e with the results of certain causes. Of medicine,
science, their whole stock of knowledge is a com-
ation of quackery and empiricism; and it is a re-
kable fact, that the healing art, which, in almost
ry other quarter of the known world, whether savage
ivilised, justly obtains for its professors the highest
ect, honours, and emolument, is in China so little
mated, that all classes are allowed to practise it *ad*
um. There are no schools for medical instruction;
theory of the human frame is wholly unknown to
m; and they even reject the doctrine of the circu-
on of the blood. Their remedies are chiefly of a
etable nature, and consist almost solely of *ginseng*
native root, which they pretend to prepare in
enty-seven different ways), rhubarb, China-root, and
. Their surgical knowledge is equally defective, as
be judged by the fact, that the practice of it is
ited almost entirely to the honourable fraternity of
bers. Their operations consist in setting a fracture,
cing a dislocation, letting blood, by scarifying, cup-
g, or acupunctuation (for they entertain a sentimental
ror of the lancet and scalpel—knife), cutting corns,

cleaning the ears, tweaking the nose, beating the back, pulling the joints till they crack; in short, we may sum up our account of Chinese knowledge of the healing art with the remark of the late Dr Gregory of Edinburgh, that "the emperor of China could not command in all his dominions such medical aid as a smart boy of sixteen, who had been apprentice for one year to a well-employed Edinburgh surgeon, would be able to afford."

LANGUAGE AND LITERATURE.

The language of the Chinese is another branch of their history, respecting which the rest of the world has been impressed with the most preposterous and exaggerated ideas. It has been represented as consisting of millions of characters—as being perfectly unattainable by foreigners, and so forth; and thus has this truly barbarous nation acquired a reputation for philological science as spurious as that which they have enjoyed for other branches of antique erudition. "It is true," as Mr Barrow says, "that their language, more than any thing else, stamps them as an original people. It has no resemblance whatever to any other language, living or dead, ancient or modern. It has neither borrowed nor lent any thing to any other nation or people, excepting to those who are unquestionably of Chinese origin. The written character is just now as distinct from any alphabetical arrangement as it was some thousands of years ago; and the spoken language has not proceeded a single step beyond the original meagre and inflexible monosyllable." All this certainly goes to prove the Chinese to be a primitive people, and so far the circumstance is a moral curiosity; but at the same time it shows their inveterate and immoveable obstinacy in adhering to a system of characters so utterly unreducible to any kind of intelligible vocabulary. The foundation of the language is purely hieroglyphic and symbolical, including all the remarkable objects of nature, such as the sun, moon, earth, fire, water, wood, stone, a horse, a cow, a dragon, &c.; the utensils most commonly in use—a knife, a spoon, a box, &c.; the primary relations of life—a father, mother, brother, son, &c.; some of the most obvious qualities of bodies, as straightness, crookedness, &c. &c. To give a detail of the history of the Chinese language, through its various modifications and arrangements, would occupy the space of volumes, and to no purpose beyond the amusement it might afford to those antiquarians who delight in the investigation of matters as frivolous as they are obsolete. Suffice it to say, that the Chinese language, which has hitherto proved such a mystery to all the rest of the world, has at length been fathomed and rendered clear by the industry of British genius. In fact, the difficulties attending the acquisition of it have proved almost altogether visionary. The industry of Dr Marshalman and Dr Morrison has supplied us with grammars and dictionaries of this singular language, and placed within our reach all the supposed treasures it contained. "Europeans," says Mr Barrow, "have been deceived as to the vast number of characters in this language, which was supposed to create its difficulty. In the great Dictionary of Kaung-hee there are not more than 40,000 characters, of which about 30,000 only are in use. The Lexicon of Scapula contains about 44,000 words, Ainsworth's Dictionary 45,000, and Johnson's about the same number. The whole works of Confucius contain only about 3000 different characters. The *Leu-lee* may have, on the whole, about 100,000 characters, but not more than 1800 different ones throughout the whole work. Where, then, can there possibly be any difficulty?" The same writer also adduces numerous instances of Europeans acquiring the Chinese language in a comparatively short time.

From all that has yet been seen, the trouble of learning the Chinese language will be very inadequately compensated by the literary "treasures" of which Mr Barrow speaks. There are no doubt a profusion of *poems* (so called), novels, histories, and dramas, &c.; *but of what character* are they! From the translations *which we have yet been* favoured with, the poems, like some of Ossian's sublime passages, consist of unintelligible imagery; their novels of silly and pointless stories; their histories, as we have already seen, of fables; and their dramas, although for the most part true to nature, yet exhibiting nature in her most revolting forms. M. de Guignes, Mr Barrow, and other visiters of Pekin assure us that the theatrical exhibitions are beyond every thing abominable and disgusting.

It has furnished matter of surprise to all writers how a government so despotic as that of China should make the cultivation of letters a subject of such special anxiety. Even the intelligent Mr Barrow makes a marvel of this fact, notwithstanding that his own writings (had we no other authority) furnish a sufficient explanation of the seeming anomaly. It is true, there is a school to be found in every village of China, and that the instruction of the pupils forms one of the most anxious concerns of the government: but what is the nature or purpose of their education? To instruct them in all the erroneous doctrines of their parents—to confine their knowledge to the native productions of Chinese writers—to make, in short, Chinese politicians of them. The boasted system of education in China is not for the purpose of enlightening the people, but of keeping them in darkness. They are allowed to know nothing of other nations, and cannot therefore comprehend their own degraded and enslaved condition.

RELIGION.

The religion of the Chinese is allied in character to the Boodhism of the Birman empire, Japan, Siam, and other parts of Eastern Asia; and, under whatever name, it may be defined as a superstition intimately associated with ceremonial observances in pagodas and temples. According to Howard Malcom, the latest authority on the subject,* the Chinese are divided into three sects, namely, those of Ju-kea-su, Taou, and Boodh.

"The Jukeasuists are the followers of Kong-foo-tse, or, as the Jesuits Latinise it, Confucius, who flourished about 560 years before Christ, and was therefore contemporary with Pythagoras. He was of royal descent, and a mandarin, but early resigned official life, and devoted himself to literature, morals, and political economy. Reducing the maxims of former sages to order, he added valuable extracts from current works, and prudent sayings of his own, and produced a digest which continues to be the *ultima thule* of Chinese piety. Travelling extensively as a popular lecturer, and sustained, not less by his high birth and eloquent address, than by the excellence of his doctrines, he soon founded a sect which became virtually the state religion. It is, however, much less intolerantly maintained than either Popery or Protestantism, where united with the state. The other religions are allowed, and sometimes fostered. Great officers, and even the emperor himself, build and endow Boodhist and Taouist temples.

The system of Confucius is highly extolled by European writers, and most extravagantly by Chinese. As accounts of it are accessible to all readers, I need not stop to describe it. He seems to have regarded religion less than politics, and the burden of his works relates to social virtues, civil government, and adherence to ancestral habits.

The sect of Taou (literally *reason*) was founded by Laou-Keum, a contemporary and rival of Confucius. His followers may be called the mystics of China. They profess alchemy, assume mysterious airs, read destinies on the palms, and make great pretensions to deep research and superior light. Their practical works contain, in general, the same laudable precepts which distinguish the system of the Ju-kea-su.

The third sect follow Fo-e, sometimes spelled *Fuh*. Foe is said to be the old orthography of *Fuh*, which is the Chinese abbreviation of *Fuh-ta*, or Boodha. The Boodhism of China is the same as that of Birmah," (for an account of which we refer to the article PAGAN RELIGIONS, in the present series of papers.) "The sys-

telligence and mildness. His age is but thirty-eight, of course endeavoured to make the visit profitable m. My heart yearned over him; and when he ed me that he meant to visit America in a year or I was happy to promise him a most cordial recep-

Priests may leave the country and return, with- he restraints which make it dangerous to others. e whole number of priests in Canton is estimated 000; of nuns, 1000. The annual expense of the temples is 250,000 dollars. An equal sum is re- ed for the periodical festivals. Half a million, ally paid in one city for religion, by pagans! And whole amount which all Christendom gives for ns in a year, is but six times as much!"

r many years, Christian missionaries of different minations have been established at Canton, Macao, other parts of China; but they make little progress roselytising the population, on account of the diffi- es of the language and the rigorous adherence of natives to ancient customs. China likewise contains Mahommedans and Jews; and these, with the stians, seem to be tolerated merely on account of ublic usefulness and learning of the missionaries ese sects. The Christians, for the same reason, are most generally respected, but have been treated, time to time, with the most arbitrary capricious- being persecuted by one emperor and encouraged nother. In the year 1747, five missionaries were aded in Fo-kien, and two Jesuits strangled in the year in Kiang-nan, all of which was done "accord- o law," which says, that the chief of any sect who ces the people from their duties under religious nces, shall be strangled.

RVIEW OF MANNERS, CHARACTER, AND CONDITION.

om all we have said, it will be evident that civili- n has as yet advanced little beyond the infancy of t may be called agricultural society in China. It be readily admitted that they were amongst the of existing nations who arrived at a certain degree cellence; but it is not less evident that they have remained stationary, and have even in some points graded. "They can only be said," observes Mr Bar- "to be great in trifles, whilst they are really trifling ery thing that is great." The following assertion r William Jones may almost be literally adopted: Their letters, if we may so call them, are merely symbols of ideas: their philosophy is in so rude a as hardly to deserve the appellation; they have ncient monuments from which their origin may be ed, even by plausible conjecture; their sciences are lly exotic; and their mechanical arts have nothing em characteristic of a particular family—nothing h any set of men in a country so highly favoured t not have discovered and improved."

their moral qualities, the Chinese are a strange pound of vanity and meanness, affected gravity and frivolity—an utter want of all manly judgment and e, combined with the most insidious art and cunning, usual accompaniments of vulgar ignorance. The ar race are distinguished by a blunt and unstudied kness of manner and openness of disposition; but true Chinese betray the most debasing servility of and manner—plausible, sly, and artful. They not the slightest regard to truth, and will assert deny any thing with the most unblushing effrontery, g also entirely destitute of shame. The pain in- ed by the bamboo is the only consideration they ch to public and disgraceful corporal punishment. y have neither sense of honour nor self-respect. Chinese prince, or powerful mandarin," says a nt traveller, "will commit extortion or oppression never he can do it with impunity, and regards it as atter of right attached to his station. A Chinese ler will cheat and defraud whenever it is in his er, and even piques himself upon his skill in over- hing, as a proof of his talent. A Chinese peasant pilfer and steal whatever is within his reach, when- r he can hope to escape detection; and the whole

nation may be affirmed to have almost nothing in view but their own self-interest and security. Their general character, in short, in point of morals, compared with the minute enforcement of duty by the penal laws, affords an irresistible proof of the utter incompetency of legislation, without the aid of religious principle, to reach beyond the mere external conduct of individuals, or to produce any thing like real social virtue among human beings." In their feelings, the Chinese are cruel, sensual, and vindictive. Mr Barrow, M. de Guignes, and other travellers, all agree in their representations of the inhuman conduct of those in authority. One of the arbitrary laws of China is the compelling of the natives to pull the imperial barges alongst the canals; and Mr Barrow had several opportunities of witnessing the merciless exercise of this authority on the part of the military. The impressed labourers took, of course, every opportunity of deserting; and whenever there was a deficiency of hands, the despotic officials set off to the nearest hamlet, roused the natives out of bed with the whip, made them jump into the water to assist the towing operations, lashing them with long cart-whips all the while with the most ruthless barbarity. Mr Barrow also relates another specimen of Chinese indifference to human life, which he witnessed in passing down the great canal betwixt Canton and Pekin. Several persons who had crowded to the brink of the canal, had posted themselves upon the high projecting stern of an old vessel, which broke down with their weight, and precipitated the whole group into the water. Although numbers of boats were plying about at the very spot, not one was observed to go to the assistance of the drowning wretches, whose shrieks and cries were totally disregarded.

Nothing is so significant of the moral condition of a people as their treatment of the female sex, and nowhere are the women so inhumanly used as in China. They are not permitted to stir out of doors, excepting the wives of the lower orders, who are to be seen toiling at all kinds of laborious tasks, while their indolent husbands are sitting quietly smoking their pipes. In the country they are even to be seen drawing the plough and harrow, while their lazy helpmate drives them on.

The practice of deforming the feet of females of the better classes has long been prevalent. While still children, the feet are bound or compressed in such a manner as completely to prevent their growth. "At five, the rich man's daughter has her foot so firmly bound, that, in the native phrase, the whole is *killed*. The foot below the instep is pressed into a line with the leg, to add to the height of the little sufferer, while two of the toes are bent under the sole, that its breadth may be only of the least dimensions. The agony of such a process it would be hard to estimate; but it is said to last about six weeks, when I suppose the wasting of all the parts, and the cessation of many of their functions, have rendered the whole insensible to pain. The development of the muscles which form the calf of the leg being checked, the limb consequently tapers from its socket down to the foot, without any risings or inflections. This is regarded as the perfection of beauty by the Chinese, who say that the knee of the female is not protuberant, like the knee of the male, and is so well covered, that she can remain kneeling a long time without inconvenience. It is perhaps less throughout its length than when the foot is allowed to retain its natural size; but whether this be from the want of exercise, which ever acts as a stimulus to muscular deformity, or from the lack of nutriment through functional disturbance, I cannot take upon me to say; but I suspect the former is the real cause; otherwise the matter would grow from bad to worse, till the whole was destroyed by atrophy. A foot two inches in length is the idol of a Chinaman, on which he lavishes the most precious *epithets which nature* and language can supply. But *its beauties are altogether ideal*; for when stripped of *its gay investments*, it is a piteous mass of lifeless *integument, which* resembles the skin of a washer-woman's hand after it has undergone a long maceration in soap and water. The sight of it is well fitted to excite our compassion, not our commendation—a beautiful limb crushed into a heap of deformity! It was the custom in former ages for the dames to wear long robes, which swept upon the ground, and kept the feet out of sight: it would be an ingenious device for the ladies to restore them again to use, and allow the instruments of progression to retain their natural size in the asylum of a long train. Poets might still celebrate the little 'golden lilies,' in conformity with hoary custom; and it would be indifferent as to the morality of the thing, whether he said a foot was only two inches long, which was thrice that length; or called that the perfection of beauty which is, in truth, only a mass of deformity." *

Amongst the other moral iniquities of the Chinese, is the crime of infanticide; and from the contempt in which females are generally held, parents expose their female children without the slightest remorse. It is a part of the duty of the Pekin police to go their rounds with carts, at an early hour of the morning, to pick up the bodies of the infants that have been thrown out into the streets in the course of the night, and to carry them, without inquiry, to a common pit without the city walls, where they are thrown in promiscuously. It has been calculated that there are between 20,000 and 30,000 female infants thus yearly sacrificed in China!

In comparison with the lower orders of the Chinese, the condition of the slaves in our West India colonies was that of princes. They have scarcely an article of furniture, besides two or three jars, a few basins of coarse earthenware, a large iron pot, a frying-pan, and a portable stove. They use neither tables nor chairs, but at meals all the family sit upon their heels round a large pot, with a bowl in each of their hands. After taking the rice from the pot with a spoon, they then take their chop-sticks, which consist of two small pieces of wood, or generally of porcupines' quills, and are held between the two first fingers of the right hand. With this strange utensil they throw their food into their mouths with remarkable expedition. Boiled rice is their staple food, with the addition of millet or barley; but they likewise eat all sorts of animal and vegetable putrescent substances. The dead hogs thrown overboard the ships in the river at Canton, are greedily picked up by the natives; and in the public market, dogs, cats, and rats, are exhibited for sale. The most degrading social vice of the Chinese is that of opium-smoking, the effects of which are much worse than those from an indulgence in intoxicating liquors.

INTERCOURSE WITH FOREIGN NATIONS—BRITISH TEA-TRADE.

The systematic discouragement which the Chinese government offers to all intercourse with foreign nations, explains the trifling amount of commerce carried on in a country adapted better than any other in the world for its prosecution, whether we consider its geographical situation, its productions, or the genius of the people. The innumerable rivers and canals with which the country is intersected, present facilities for internal communication possessed by no other country; yet there is no regular system of trade amongst them; it consists almost solely of barter, there being no circulating medium, excepting a small copper coin, the value of which is almost too minute for calculation. It is reckoned, that on the grand Pekin canal there are upwards of 10,000 boats and barges of various descriptions continually employed in the interchange of national produce. Of the commercial capabilities of China, indeed, we have ample evidence in the immense number and crowded state of the cities. These are divided by the Chinese into three classes, according to the number of leagues which they occupy; and of the first class alone —or *imperial* cities, as they term them—the natives enumerate upwards of 4000. There is much exaggeration here, no doubt; but, even estimating the number

* Lay's "Chinese as they are."

reigners are not permitted to go ashore and re-
al pleasure at Canton. Their only land establish-
ts consist of hongs or factories, which extend in a
along the banks of the river, from which they are
ut about a hundred yards. They are built on a broad
, with a spacious promenade in front. The hongs
ctories individually consist of courts or lanes, ad-
ing of no thoroughfare, and solely dedicated to the
mmodation of the foreign residents. Large ware-
es for the reception of goods are adjacent. The
e of the Chinese suburbs which is most frequented
reigners, is termed China Street, consisting entirely
hops, in which the native dealers are to be seen
d from morning till night. Their tricks in entrap-
British seamen into purchasing their commodities,
long been matter of notoriety. Their signs usu-
ly exhibit an English name as well as a Chinese
and having picked up an acquaintance with the
familiar of Jack's expressions, their mode of ad-
ing their rough customers evinces at once the
ty and unscrupulous disposition of the natives.
he manner in which foreigners have heretofore con-
ed business at Canton is as follows:—When a ship
ves, it is necessary immediately to get a native mer-
t (or, as he is called, a hong merchant) to become
rity for the import and export dues, as well as for
good behaviour of the crew. In this there is never
d the slightest difficulty, there being, on the con-
y, always a competition amongst the natives for the
nor of a consignment. The import duties consist of
upon the different species of goods, as well as a
age upon the vessel. In addition to the tonnage and
o charges, there is also levied what is called a *kum-
*, or present to government, exigible from ships of
y burden alike. It has been estimated that all these
ous port charges, including the expenses of victual-
this ships, &c., amount to about 7000 dollars on
ip of 400 tons register.
he foreign merchants at Canton consist of British,
rican, French, Dutch, Danish, Swedish, Spanish,
uguese, and Indian British subjects, who in 1832
unted to 110. There are eight British establish-
ts, seven American, and one joint Dutch and French
blishment. Two English newspapers are published
anton; the Canton Register once a-fortnight, and
Chinese Courier once a-week.
he personal intercourse of Europeans with the
ese at Canton is chiefly carried on by means of a
erish (for it cannot be called a language) composed
nglish, Portuguese, Chinese, and other words, but
whole greatly broken or altered in sound, and pos-
ing no sort of grammatical construction.
t the entrance to an estuary of the river on which
ton is situated, is the island of Macao, containing a
of the same name, part of which forms a settle-
t or tenancy of the Portuguese, and here also the
llies of European merchants at Canton have been
ired to reside. The Portuguese privileges have
latterly much circumscribed, and their trade
tly diminished. "From Macao to the Boca Tigris
rue entrance of the river [proceeding upwards] is
forty miles, affording a very safe channel for the
est ships. As far as the Boca or Bogue, the whole
broad estuary of the sea, interspersed with islands,
hich the well-known Lintin lies just midway between
ao and the Bogue. Lintin is on the right of the
nel for ships, and abreast of it on the left is Lankeet
nd, forming behind it the harbour of Kumsing-moon,
re the opium ships of late years were accustomed to
t anchor in safety. There is no entrance to the Can-
river to the eastward of the Boca Tigris; but on the
the case is widely different; and it is there that
principal difficulties of a blockading squadron exist.
main part of the river flows through the Bogue;
to the westward there stretches a great delta, which
been gradually formed by depositions of soil from
turbid waters, and is crossed in all directions by
llow channels communicating with each other and
h Canton. Some of these channels form the inner

passage, by which the British traders used generally to proceed between Canton and Macao, passing a town called Heang-shan, the residence of the chief magistrate of the Macao district. These shallow channels to the westward, though they are impassable by English ships, present no obstacle to the flat-bottomed trading craft of the Chinese, below the size of the larger junks."*

It has been by means of the navigable inlet thus described, that nearly all intercourse with the Chinese has taken place; all the other ports which lie to the northward being shut against European commerce. The greatest possible care has at least been taken to prevent any intercourse by the river Yang-tse-Keang, which, by its connexion with the great canal, leads to Pekin and the chief northern districts.

The principal traders with the Chinese have latterly been the Americans and British. "The American intercourse with China," says M'Culloch, "commenced shortly after the termination of the revolutionary war, and has since gone on rapidly increasing, so as to constitute one of the most valuable branches of the trade of the United States." Mr M'Culloch gives a table showing the extent of the exports from Canton to America from 1804 to 1826–7, by which, in the last-mentioned year, it is seen that the Americans had twenty-six ships in the tea-trade, and that the total value of exports from China was 4,363,788 dollars. "The principal articles," continues this most accurate authority, "carried by the Americans to China, are bullion, furs, Turkey opium, English woollens and cottons, and ginseng. The commodities exported by the Americans from China are tea, nankeens, raw and wrought silk, sugar, cassia, and camphor, with minor articles." The Americans are exceedingly enterprising in this, as in every other trade in which they engage.

The British trade with Canton was formerly carried on by the East India Company, but by an act of parliament which came into operation in April 1834, the trade was thrown open to all classes of British subjects. From enjoying a monopoly, the East India Company were the only sellers of tea in this country, and could therefore regulate the price as they thought proper. It is but fair to say, that the Company did not abuse this monopoly; but, from the expensive manner in which the trade was carried on at Canton, the price of tea was greater in this country than it has been since competition was allowed. The duty on tea, down to the 22d April 1834, was 96 per cent. on all teas sold under two shillings a-pound, and 100 per cent. on all that were sold at or above two shillings. A discriminating scale of duties was afterwards established, with a view to allow the introduction of the cheapest kind of tea at the lowest duty; but it was found that merchants did not scruple to introduce better qualities of the article under inferior denominations; and to put an end to this impropriety, as well as stop all clamour on the subject, a statute was passed (1836), enacting that 2s. 1d. per lb. should be charged on all teas without exception, entered for home consumption in the United Kingdom. In 1835, the first year of open trade in tea, the imports to the United Kingdom amounted to 43,000,000 lbs., being more than 10,000,000 above what had ever been imported in any single year by the East India Company. In 1837, the imports were 36,973,981 lbs. (of which 30,625,206 were retained for home consumption), and the duties produced a revenue of £3,223,840. In exchange for the tea brought from China, there is imported into that country woollen and cotton articles, copper, iron, lead, glass, earthenware, and jewellery, the value of which in 1831 was £593,755. Bullion used formerly to be sent to China; but of late years it has been imported from China into England, instead of the contrary.

The preceding details refer to that condition of affairs which prevailed previously to 1838–9, when British intercourse with China was suddenly brought to a close *by events* consequent on the forcible suppression of the "opium-trade." As already mentioned, the C indulge in opium-smoking, but from the injurio of the practice, it is ostensibly prohibited, and th duction of the article is legally declared to be cont Notwithstanding the illegality of the traffic, h it has ever been extensively carried on, not in but open manner, by smuggling-vessels on th Remonstrances against it by the Chinese gove were generally disregarded, because the manda others sanctioned it for private reasons; and observed that all menaces on the subject were empty threats, apparently put forward for the external decency. Lulled into fancied securi feeling that they were more encouraged than raged, the British continued to pour in opium fro till, by a sudden outbreak, the whole stock in th at Canton was seized and publicly burnt, causin of from two to three millions of pounds sterlin parties interested. It is here necessary to menti the chief promoters of the opium trade were India Company, and the stoppage of it was prove most disastrous to British interests in th empire. The rajahs and petty princes of Hind the chief growers of the poppy, and it is impo conciliate their favour. The best opium is pro Malwa, a district of India. From that quarte at Bombay a duty of 125 rupees (£12, 10s.) p fetching in that market from 400 to 500 rup to £50). This quantity sells on the Chinese 700 dollars (£151, 5s. 4d.), and perhaps muc The temptation to get so large a profit sets all stopping the trade at defiance. "The opiu (observes Lord Jocelyn),* however hateful ma in the eyes of many, is, it must be recollected, of great benefit to the Indian government, ret have heard, a revenue of upwards of two mill a half yearly. It therefore becomes those wh eager for its suppression to point out some m making up the serious defalcation of revenue t necessarily accrue to the Indian governmen expenses already outrun its present income."

The seizure and destruction of the opium, known, precipitated a quarrel with China, whic (May 1841) far from being settled to the satisf the British people and government. The conte manner in which the Chinese have always tre English as well as other Europeans, has tended to aggravate the dispute. Puffed up with a degree of vanity, the Chinese government has the habit of treating and speaking of the Englis *barians*, and has on no account allowed the se of a consul or ambassador to watch over Briti rests. The only channel of communication h by a Chinese commissioner at Canton and a sioner or envoy from Britain, who in late ti not allowed to land. Added to this, the mean cun deceit of the Chinese have proved an obstacle t kind of fair negotiation. The depreciatory vie of the English power having frustrated the adjustment of the dispute, nothing was left the but to compel attention to their claims for compe and an apology for indignities, by force of arms. quently, the year 1840 was destined to present traordinary spectacle of a British naval and force on the coast of China. Chusan, an islan coast, was captured in the month of July, after resistance, and various other successes attended tish arms in a few months afterwards. Up till th we write, however, owing to the temporising the British commissioner, nothing definite has in the war, and we therefore leave it to the e events. Meanwhile, the tea-trade has suff material interruption, as it has been carried great measure under cover of other flags than tish, though with a loss to British naval interes

TIDES.

e waters of the sea may exhibit to the eye a calm
illed surface when not agitated by winds, but they
ever altogether still. Their ceaseless motion, which
he important effect of preserving them from stag-
n, is caused by two great risings and depressions,
wings and ebbings, of the waters, in the course of
ty-four hours, known by the name of tides. The
tides or flowings of the sea are experienced daily
ver the globe, though in some seas, from peculiar
causes, they are less powerful than in other places.
not a little remarkable that the condition of high
r or full tide occurs at directly opposite sides of
arth at the same time. When it is high water at
tude 0, it is also high water at longitude 180, and
with every other two opposite points of the earth,
e same parallel of latitude.

has been ascertained, beyond all reasonable doubt,
the tides are caused by the attractive influence of
noon. By the universal law of attraction or gravi-
n, all masses of matter have a tendency to be
cted or drawn towards each other. The moon,
efore, as a mass of matter, in passing round the
n, has a tendency to draw the earth after it, or out
s natural relative position, and it really does so to
all extent. As it passes round, it draws up the
rs in a protuberance, or, in common language, draws
ge wave after it. But it also draws the land be-
h the protuberance, and so causes the opposite side
e globe to be drawn away from the ocean, leaving
waters there to form a similar protuberance or high
. In the one case, the water is drawn directly up
wards the moon; in the other, the water is in some
e left behind by the land being pulled away from
In both a similar effect is produced; two high
are caused at opposite extremities of the earth.

between those two points. A tide requires six hours to rise, which it does by small impulses or ripplings of the water on the shore, and six hours to ebb or fall; but every successive high water is from twenty to twenty-seven minutes later than the preceding, or, on an average, about fifty minutes for two tides, in consequence of the earth requiring that time above the twenty-four hours to bring any given point again beneath the moon. The tides are thus retarded by the same reason that the moon rises fifty minutes later every day. It is evident that the tides will be greatest at that point of the earth's surface which is nearest to the moon, or where the latter is vertical. She is so between the tropics; and accordingly the tides are there greatest, and they diminish as we approach either poles. It is further to be remarked, that the moon does not anywhere draw up the tides immediately. Three hours elapse before the waters are raised, in consequence of the law of inertia, or a disposition which every body has to continue in the condition of rest or motion in which it happens to be placed. This stubbornness to resist the moon's influence is only overcome by a three hours' action upon the waters; and thus the tidal wave is always three hours behind the moon in its passage. Twice a-year, namely, in March and September, the tides are higher than at other times, because then the attraction of the sun and moon are strongest. In some of the firths or arms of the sea on the east coast of Scotland, it has been occasionally noticed that there have been four high waters in the twenty-four hours. These, however, are not simple tides. The double risings are caused by the irregular passage of the tidal wave from the Atlantic round the north and south points of the island of Great Britain. When that portion of the wave which proceeds by the south reaches the east coast sooner than that by the north, or vice versa, there will be two risings of the water instead of one. A similar phenomenon may perhaps be observed in other parts of the earth. In the Mediterranean Sea the tides are small, and in some places scarcely perceptible; this is caused by the general confinement of that inland branch of the ocean by the Straits of Gibraltar, which prevent the full action of the tidal wave either in its rising or recession.

CURRENTS.

Gulf Stream, which is perhaps the mos
current in the world.

It is obvious, that to the mariner
be of great importance. From Portuga
ships have sailed to the Bights of
Guinea coast, being 150 leagues, in tw
they could not return in less than seve

early ages of their art. Men could onl
such places in early ages by the curre
and air; and thus the cultivation of large
regions must have commenced much earl
have otherwise been the case.

Besides the grand equatorial or tro
there is one of a less decided character
to the equator. The sea under the trop
to a greater extent than elsewhere, by

r, on arriving at which they are dispersed into aqueo-
vapours, and rise whirling round in a spiral direc-
towards the cloud. This conical ascending column
et by another descending column, which leans to-
ls the water, and joins with it. In many cases the
ne column is from fifty to eighty toises (fathoms)
ameter near its base. Both columns, however,
nish towards the middle, where they unite; as
here they are not more than three or four feet
ameter. The entire column presents itself in the
e of a hollow cylinder, or tube of glass empty within.
ides over the sea without any wind being felt; in-
several have been seen at once following different
tions. When the cloud and the marine base of
aterspout move with unequal velocities, the lower
is often seen to incline sideways, or even to bend,
inally to burst in pieces. A noise is then heard
the noise of a cataract falling in a deep valley.
ning frequently issues from the very bosom of
waterspout, particularly when it breaks; but no
der is ever heard."

ilors, to prevent the imminent danger which their
ls would be exposed to by coming in contact with
tremendous columns, discharge upon them a
n ball, which, passing through them, causes them
riably to burst, and consequently removes all
e of injury connected with them. This pheno-
n is accounted for in the following manner:—
winds meet—a vortex ensues; any cloud which
ens to lie between them is condensed into a coni-
rm, and turned round with great velocity: this
ling motion drives from the centre of the cloud all
articles contained in it; a vacuum is thereby pro-
d, and water, or any other body lying beneath this
um, is carried into it upon the usual and well-
n principle. The cannon ball, breaking this cylin-
which is always partly hollow, causes it to fall to
s, in the same manner as a touch upon the surface
soap-ball reduces the resplendant mass to a drop
mmon water.

TEMPERATURE OF THE SEA.

e temperature of the sea, like that of the air, is
to be affected by the latitude and the season of
ear, but not to nearly so great an extent as the
Within the tropics, where the season has hardly
influence, it is generally found at about 80 or 81
ahrenheit's thermometer, being somewhat more,
neral, than the warmth of the neighbouring air,
is deprived to a certain extent of its heat, in
to carry on the process of evaporation. Taking
onth of March as one of those during which the
of the sun must be equally determined in both
tions by latitude, we find that in that month the
as been found, at 11° 32′ south, of 80.6 Fahren-
at 31° 34′ south, of 73.7; at 40° 36′ south, of
; though in some instances it has been found
al degrees more or less at the same season, and
r nearly the same latitude. The chief cause of
ariation is the perpetual flow of water from the
to the equator, which has been already explained.
s been pretty nearly ascertained, that, in the tro-
seas, it ranges about 9 degrees of Fahrenheit; in
iddle of the temperate zone about 12; and after
decreases with a more rapid and more equable
tion. The temperature of the sea is also affected
depth. In deep seas between the tropics, the
diminishes towards the bottom; while, in more
latitudes, it is sometimes observed to become
er. The sea is a bad conductor of heat; the
rays can only penetrate about three hundred feet
the surface, nor does the light descend any
r. A small difference is discovered between the
vations on temperature in the two hemispheres.
he first 25° towards the south, the decrease of
is slower, and after that more rapid, than towards
orth.

must be evident to every one who considers the
mass of waters composing the ocean, and the

cleaning the ears, tweaking the nose, beating the back, pulling the joints till they crack; in short, we may sum up our account of Chinese knowledge of the healing art with the remark of the late Dr Gregory of Edinburgh, that "the emperor of China could not command in all his dominions such medical aid as a smart boy of sixteen, who had been apprentice for one year to a well-employed Edinburgh surgeon, would be able to afford."

LANGUAGE AND LITERATURE.

The language of the Chinese is another branch of their history, respecting which the rest of the world has been impressed with the most preposterous and exaggerated ideas. It has been represented as consisting of millions of characters—as being perfectly unattainable by foreigners, and so forth; and thus has this truly barbarous nation acquired a reputation for philological science as spurious as that which they have enjoyed for other branches of antique erudition. "It is true," as Mr Barrow says, "that their language, more than any thing else, stamps them as an original people. It has no resemblance whatever to any other language, living or dead, ancient or modern. It has neither borrowed nor lent any thing to any other nation or people, excepting to those who are unquestionably of Chinese origin. The written character is just now as distinct from any alphabetical arrangement as it was some thousands of years ago; and the spoken language has not proceeded a single step beyond the original meagre and inflexible monosyllable." All this certainly goes to prove the Chinese to be a primitive people, and so far the circumstance is a moral curiosity; but at the same time it shows their inveterate and immoveable obstinacy in adhering to a system of characters so utterly unreducible to any kind of intelligible vocabulary. The foundation of the language is purely hieroglyphic and symbolical, including all the remarkable objects of nature, such as the sun, moon, earth, fire, water, wood, stone, a horse, a cow, a dragon, &c.; the utensils most commonly in use—a knife, a spoon, a box, &c.; the primary relations of life—a father, mother, brother, son, &c.; some of the most obvious qualities of bodies, as straightness, crookedness, &c. &c. To give a detail of the history of the Chinese language, through its various modifications and arrangements, would occupy the space of volumes, and to no purpose beyond the amusement it might afford to those antiquarians who delight in the investigation of matters as frivolous as they are obsolete. Suffice it to say, that the Chinese language, which has hitherto proved such a mystery to all the rest of the world, has at length been fathomed and rendered clear by the industry of British genius. In fact, the difficulties attending the acquisition of it have proved almost altogether visionary. The industry of Dr Marshalman and Dr Morrison has supplied us with grammars and dictionaries of this singular language, and placed within our reach all the supposed treasures it contained. "Europeans," says Mr Barrow, "have been deceived as to the vast number of characters in this language, which was supposed to create its difficulty. In the great Dictionary of Kaung-hee there are not more than 40,000 characters, of which about 30,000 only are in use. The Lexicon of Scapula contains about 44,000 words, Ainsworth's Dictionary 45,000, and Johnson's about the same number. The whole works of Confucius contain only about 3000 different characters. The *Leu-lee* may have, on the whole, about 100,000 characters, but not more than 1860 different ones throughout the whole work. Where, then, can there possibly be any difficulty?" The same writer also adduces numerous instances of Europeans acquiring the Chinese language in a comparatively short time.

From all that has yet been seen, the trouble of learning the Chinese language will be very inadequately compensated by the literary "treasures" of which Mr Barrow speaks. There are no doubt a profusion of poems (so called), novels, histories, and dramas, &c.; but of what character are they? From the translations which we have yet been favoured with, the poems, like some of Ossian's sublime passages, consist of gible imagery; their novels of silly and pointles their histories, as we have already seen, of fal their dramas, although for the most part true yet exhibiting nature in her most revolting fo de Guignes, Mr Barrow, and other visiters assure us that the theatrical exhibitions ar every thing abominable and disgusting.

It has furnished matter of surprise to al how a government so despotic as that of Chi make the cultivation of letters a subject of suc anxiety. Even the intelligent Mr Barrow mak vel of this fact, notwithstanding that his own (had we no other authority) furnish a sufficie nation of the seeming anomaly. It is true, t school to be found in every village of China, the instruction of the pupils forms one of anxious concerns of the government: but wh nature or purpose of their education? To instr in all the erroneous doctrines of their parents. fine their knowledge to the native productions o writers—to make, in short, Chinese politicians The boasted system of education in China is n purpose of enlightening the people, but of keep in darkness. They are allowed to know nothing nations, and cannot therefore comprehend th degraded and enslaved condition.

RELIGION.

The religion of the Chinese is allied in cha the Boodhism of the Birman empire, Japan, S other parts of Eastern Asia; and, under whatev it may be defined as a superstition intimately as with ceremonial observances in pagodas and According to Howard Malcom, the latest auth the subject,* the Chinese are divided into thr namely, those of Ju-kea-su, Taou, and Boodh.

"The Jukeasuists are the followers of Kong or, as the Jesuits Latinise it, Confucius, who fl about 560 years before Christ, and was theref temporary with Pythagoras. He was of royal and a mandarin, but early resigned official devoted himself to literature, morals, and politi nomy. Reducing the maxims of former sages t he added valuable extracts from current wor prudent sayings of his own, and produced which continues to be the *ultima thule* of Chines Travelling extensively as a popular lecturer, a tained, not less by his high birth and eloquent than by the excellence of his doctrines, he soon a sect which became virtually the state religion however, much less intolerantly maintained tha Popery or Protestantism, where united with th The other religions are allowed, and sometimes f Great officers, and even the emperor himself, b endow Boodhist and Taouist temples.

The system of Confucius is highly extolled by pean writers, and most extravagantly by Chines accounts of it are accessible to all readers, I n stop to describe it. He seems to have regarded less than politics, and the burden of his works to social virtues, civil government, and adher ancestral habits.

The sect of Taou (literally *reason*) was foun Laou-Keum, a contemporary and rival of Co His followers may be called the mystics of China profess alchemy, assume mysterious airs, read d on the palms, and make great pretensions to d search and superior light. Their practical wor tain, in general, the same laudable precepts whi tinguish the system of the Ju-kea-su.

The third sect follow Fo-e, sometimes spelle Foe is said to be the old orthography of *Fuh*, w the Chinese abbreviation of *Fuh-ta*, or Boodha. Boodhism of China is the same as that of Bi (for an account of which we refer to the article RELIGIONS, in the present series of papers.) "T

* Travels in Hindustan and China. (People's Editio

tism is certainly far older than either of the others. It is generally supposed to have been introduced about A.D. 70. Kempfer dates the introduction about A.D. 518, when 'Darma, a great saint, came from the west, and laid the foundation,' &c. Chinese historians agree that the worship of Fohi was originally brought from India. Sir William Jones says confidently, 'Boodh was unquestionably the Fo-e of China.'

This sect probably embraces one-third of the entire population. The government acts with indecision towards it, at one time denouncing it as dangerous, and at another contributing to its support. M. Gutzlaff saw at Pooto some placards calling on the people, in the name of the emperor, to repair to the Boodhist temple of that place, in order to propitiate Heaven for a fruitful spring. The priests are numerous, but not greatly respected. I saw some of them in the streets daily. A few were exceedingly well-dressed, but generally they were both shabby and dirty, sometimes quite ragged."

Mr Malcom gives the following account of a visit to a Boodhist temple at Canton:—"There are 124 temples in Canton, besides the numerous public altars seen in the streets. I saw the principal ones without the walls, which are said not to be inferior, on the whole, to those within. They strikingly resemble the monasteries of Europe. The handsomest is one of the Boodhists, in the suburb of Ho-nan, on the opposite side of the river. Being accompanied by Messrs Bridgman, Parker, and Morrison, who were acquainted with the superior, I was not only shown every part by his order, but had the pleasure of his society for an hour. Cloisters, corridors, courtyards, chapels, image-houses, and various offices, are scattered, with little regard to order, over a space of five or six acres. Priests, with shaven crowns and rosaries, loitered about; but I never saw common people come to worship either at this or other establishments. Some of the priests occupied small and mean apartments; but those of the superior are spacious, and furnished not only with the ordinary conveniences, but with chandeliers, mirrors, pictures, &c., and with an extensive library. The buildings are chiefly of brick, one storey high, the walks handsomely flagged, and the courtyard ornamented with large trees, or beautiful parterres of flowers. The printing-office contains stereotype plates enough to load a small vessel, so arranged as that every work is readily accessible. The principal apartment or temple is about 100 feet square, with the usual images, &c. We attended here to witness the regular evening service. It seemed to create little interest, for out of 160 resident priests, there were but fifty present; and these uttered their repetitions with the most obvious indifference. Their prayers are in Pali ostensibly, but I am told not truly, as their mode of writing renders it utterly unintelligible to any one. They keep time by striking a wooden drum, and occasionally a bell. At a certain stage of the process, the whole company formed into single file, and marched round the hall, without ceasing their repetitions. This gave us a full view of their countenances; and so far as these indicated, a more stupid set could not be picked out in all Canton. I have already remarked this characteristic of the Boodhist priesthood in other countries, and am confirmed in the belief of its being attributable to the character of their religion, and the nature of their duties.

Instead of the humble dress of Birman and Siam priests, these wear as handsome as they can get, with shoes and stockings. What is worse, some are in rags, barefoot, and squalid, with apparent poverty. They have, however, a common refectory, where I presume all fare alike. The buildings were erected at different times by the munificence of individuals, and by the revenues of the establishment, which amount to about 8000 dollars per annum.

While we walked over the premises, the superior had prepared us a repast of sweetmeats and fruits, to which he sat down with us. His manners were easy and elegant, his dress unostentatious, and his countenance full of intelligence and mildness. His age is but thirty-eight. We of course endeavoured to make the visit profitable to him. My heart yearned over him; and when he assured me that he meant to visit America in a year or two, I was happy to promise him a most cordial reception. Priests may leave the country and return, without the restraints which make it dangerous to others.

The whole number of priests in Canton is estimated at 2000; of nuns, 1000. The annual expense of the 124 temples is 250,000 dollars. An equal sum is required for the periodical festivals. Half a million, annually paid in one city for religion, by pagans! And the whole amount which all Christendom gives for pagans in a year, is but six times as much!"

For many years, Christian missionaries of different denominations have been established at Canton, Macao, and other parts of China; but they make little progress in proselytising the population, on account of the difficulties of the language and the rigorous adherence of the natives to ancient customs. China likewise contains some Mahommedans and Jews; and these, with the Christians, seem to be tolerated merely on account of the public usefulness and learning of the missionaries of these sects. The Christians, for the same reason, are the most generally respected, but have been treated, from time to time, with the most arbitrary capriciousness, being persecuted by one emperor and encouraged by another. In the year 1747, five missionaries were beheaded in Fo-kien, and two Jesuits strangled in the same year in Kiang-nan, all of which was done "according to law," which says, that the chief of any sect who seduces the people from their duties under religious pretences, shall be strangled.

REVIEW OF MANNERS, CHARACTER, AND CONDITION.

From all we have said, it will be evident that civilisation has as yet advanced little beyond the infancy of what may be called agricultural society in China. It may be readily admitted that they were amongst the first of existing nations who arrived at a certain degree of excellence; but it is not less evident that they have long remained stationary, and have even in some points retrograded. "They can only be said," observes Mr Barrow, "to be great in trifles, whilst they are really trifling in every thing that is great." The following assertion of Sir William Jones may almost be literally adopted:—"Their letters, if we may so call them, are merely the symbols of ideas: their philosophy is in so rude a state as hardly to deserve the appellation; they have no ancient monuments from which their origin may be traced, even by plausible conjecture; their sciences are wholly exotic; and their mechanical arts have nothing in them characteristic of a particular family—nothing which any set of men in a country so highly favoured might not have discovered and improved."

In their moral qualities, the Chinese are a strange compound of vanity and meanness, affected gravity and real frivolity—an utter want of all manly judgment and sense, combined with the most insidious art and cunning, the usual accompaniments of vulgar ignorance. The Tartar race are distinguished by a blunt and unstudied frankness of manner and openness of disposition; but the true Chinese betray the most debasing servility of tone and manner—plausible, sly, and artful. They have not the slightest regard to truth, and will assert and deny any thing with the most unblushing effrontery, being also entirely destitute of shame. The pain inflicted by the bamboo is the only consideration they attach to public and disgraceful corporal punishment. They have neither sense of honour nor self-respect. "A Chinese prince, or powerful mandarin," says a recent traveller, "will commit extortion or oppression whenever he can do it with impunity, and regards it as a matter of right attached to his station. A Chinese trader will cheat and defraud whenever it is in his power, and even piques himself upon his skill in overreaching, as a proof of his talent. A Chinese peasant will pilfer and steal whatever is within his reach, whenever he can hope to escape detection; and the whole

nation may be affirmed to have almost nothing in view but their own self-interest and security. Their general character, in short, in point of morals, compared with the minute enforcement of duty by the penal laws, affords an irresistible proof of the utter incompetency of legislation, without the aid of religious principle, to reach beyond the mere external conduct of individuals, or to produce any thing like real social virtue among human beings." In their feelings, the Chinese are cruel, sensual, and vindictive. Mr Barrow, M. de Guignes, and other travellers, all agree in their representations of the inhuman conduct of those in authority. One of the arbitrary laws of China is the compelling of the natives to pull the imperial barges alongst the canals; and Mr Barrow had several opportunities of witnessing the merciless exercise of this authority on the part of the military. The impressed labourers took, of course, every opportunity of deserting; and whenever there was a deficiency of hands, the despotic officials set off to the nearest hamlet, roused the natives out of bed with the whip, made them jump into the water to assist the towing operations, lashing them with long cart-whips all the while with the most ruthless barbarity. Mr Barrow also relates another specimen of Chinese indifference to human life, which he witnessed in passing down the great canal betwixt Canton and Pekin. Several persons who had crowded to the brink of the canal, had posted themselves upon the high projecting stern of an old vessel, which broke down with their weight, and precipitated the whole group into the water. Although numbers of boats were plying about at the very spot, not one was observed to go to the assistance of the drowning wretches, whose shrieks and cries were totally disregarded.

Nothing is so significant of the moral condition of a people as their treatment of the female sex, and nowhere are the women so inhumanly used as in China. They are not permitted to stir out of doors, excepting the wives of the lower orders, who are to be seen toiling at all kinds of laborious tasks, while their indolent husbands are sitting quietly smoking their pipes. In the country they are even to be seen drawing the plough and harrow, while their lazy helpmate drives them on.

The practice of deforming the feet of females of the better classes has long been prevalent. While still children, the feet are bound or compressed in such a manner as completely to prevent their growth. "At five, the rich man's daughter has her foot so firmly bound, that, in the native phrase, the whole is *killed*. The foot below the instep is pressed into a line with the leg, to add to the height of the little sufferer, while two of the toes are bent under the sole, that its breadth may be only of the least dimensions. The agony of such a process it would be hard to estimate; but it is said to last about six weeks, when I suppose the wasting of all the parts, and the cessation of many of their functions, have rendered the whole insensible to pain. The development of the muscles which form the calf of the leg being checked, the limb consequently tapers from its socket down to the foot, without any risings or inflections. This is regarded as the perfection of beauty by the Chinese, who say that the knee of the female is not protuberant, like the knee of the male, and is so well covered, that she can remain kneeling a long time without inconvenience. It is perhaps less throughout its length than when the foot is allowed to retain its natural size; but whether this be from the want of exercise, which ever acts as a stimulus to muscular deformity, or from the lack of nutriment through functional disturbance, I cannot take upon me to say; but I suspect the former is the real cause; otherwise the matter would grow from bad to worse, till the whole was destroyed by atrophy. A foot two inches in length is the idol of a Chinaman, on which he lavishes the most precious epithets which nature and language can supply. But its beauties are altogether ideal; for when stripped of its gay investments, it is a piteous mass of lifeless integument, which resembles the skin of a washer-woman's hand after it has undergone a long macer tion in soap and water. The sight of it is well fit to excite our compassion, not our commendation- beautiful limb crushed into a heap of deformity! was the custom in former ages for the dames to we long robes, which swept upon the ground, and kept t feet out of sight: it would be an ingenious device f the ladies to restore them again to use, and allow t instruments of progression to retain their natural s in the asylum of a long train. Poets might still cel brate the little 'golden lilies,' in conformity with hon custom; and it would be indifferent as to the morali of the thing, whether he said a foot was only two inch long, which was thrice that length; or called that t perfection of beauty which is, in truth, only a mass deformity." *

Amongst the other moral iniquities of the Chines is the crime of infanticide; and from the contempt which females are generally held, parents expose the female children without the slightest remorse. It is part of the duty of the Pekin police to go their roun with carts, at an early hour of the morning, to pick u the bodies of the infants that have been thrown out in the streets in the course of the night, and to carry the without inquiry, to a common pit without the city wal where they are thrown in promiscuously. It has be calculated that there are between 20,000 and 30,0 female infants thus yearly sacrificed in China!

In comparison with the lower orders of the Chines the condition of the slaves in our West India colon was that of princes. They have scarcely an article furniture, besides two or three jars, a few basins coarse earthenware, a large iron pot, a frying-pan, a a portable stove. They use neither tables nor chair but at meals all the family sit upon their heels round large pot, with a bowl in each of their hands. Aft taking the rice from the pot with a spoon, they then ta their chop-sticks, which consist of two small pieces wood, or generally of porcupines' quills, and are he between the two first fingers of the right hand. Wi this strange utensil they throw their food into the mouths with remarkable expedition. Boiled rice their staple food, with the addition of millet or barley but they likewise eat all sorts of animal and vegetab putrescent substances. The dead hogs thrown ove board the ships in the river at Canton, are greedi picked up by the natives; and in the public marke dogs, cats, and rats, are exhibited for sale. The mo degrading social vice of the Chinese is that of opium smoking, the effects of which are much worse than thos from an indulgence in intoxicating liquors.

INTERCOURSE WITH FOREIGN NATIONS—BRITISH TEA-TRADE.

The systematic discouragement which the Chines government offers to all intercourse with foreign n tions, explains the trifling amount of commerce carrie on in a country adapted better than any other in th world for its prosecution, whether we consider i geographical situation, its productions, or the genius the people. The innumerable rivers and canals wit which the country is intersected, present facilities fo internal communication possessed by no other country yet there is no regular system of trade amongst them it consists almost solely of barter, there being no ci culating medium, excepting a small copper coin, th value of which is almost too minute for calculation. is reckoned, that on the grand Pekin canal there ar upwards of 10,000 boats and barges of various descri tions continually employed in the interchange of nation produce. Of the commercial capabilities of China, in deed, we have ample evidence in the immense numbe and crowded state of the cities. These are divided b the Chinese into three classes, according to the numbe of leagues which they occupy; and of the first class alon —or *imperial* cities, as they term them—the native enumerate upwards of 4000. There is much exagge ration here, no doubt; but even estimating the numbe

* Lay's "Chinese as they are."

communities at a third, or even a fourth, of
set down by the Chinese, what an enormous
f consumption for all the necessaries of life is
wn! What an unbounded mart for all kinds
h manufactures would be thrown open by the
of the government restrictions upon commerce!
e people of China are anxious for this free in-
e with other nations, has been abundantly
and in fact their greedy and peculatory dispo-
fficiently guarantees the readiness with which
uld engage in foreign traffic. But the all-
. constraints of the government hang like a mill-
and their necks. Whatever be the ignorance
wer classes, there is no want of enlightenment
:ecutive, which is conscious that a free trade
evitably lead to the breaking up of the whole
system of ruling. Their jealousy, indeed, is not
to be wondered at, considering the precedent
hem in the rise of the British power in the
ring peninsula of India; the only wonder is,
d all the turmoils of war which have disturbed
d during so many ages, this country, so fertile
' thing which can make a country desirable,
ave remained comparatively unmolested.
vell known that the foreign trade of China is
exclusively to one port—that of Canton. The
l trade with Russia and India has now almost
ceased. So great is their jealousy of the Rus-
deed, that the latter are the only people inter-
om even visiting Canton.
oes not appear to have been known in Britain
to 1650; and it is evident, from the following
Mr Pepys' Diary, that many years elapsed pre-
o its coming into general use:—"September 25,
[sent for a cup of tea (a China drink), of which
never drunk before." And in 1664, there is
made of the East India Company commission-
e foreign agent to purchase 2 lbs. 2 oz. of tea
sent to his majesty! From this time forward,
, the consumption of tea increased with a rapi-
rcely less wonderful than the progress of the
cotton manufacture.
n, at which the principal foreign commerce
d on by the Chinese, and at which all the ex-
tea take place, is situated on the eastern bank
river Pekiang, a beautiful placid stream, as
the Thames at London. This great outlet of
trade is about 400 miles in length, and Canton
t the distance of 80 miles from its mouth. Can-
ists of two descriptions of towns—that which
ed by walls, and the suburbs; both together,
said to contain from seven to eight hundred
d inhabitants. The circuit of the walls, which
moderate height, and furnished with a few
is estimated by some at five, and by others at
les. Only about a third part, however, of the
nclosed is covered with buildings; the rest is
l with pleasure-grounds and fish-ponds. The
uring country is very charming—hilly towards
, and presenting in that quarter a beautiful
t. The streets are long and narrow; the houses
y low, and towering above them may be seen
and pagodas. At night the gates are closed, and
own across the entrance to the streets. From
losed city, as well as from every other town in
ll foreigners are rigorously excluded; and these,
obtain permission, must take up their abode
burbs, which contain a very miscellaneous popu-
ough not therefore inferior in point of accommo-
r appearance. But the most curious particular
ng Canton is the existence of a floating town on
r, consisting of perhaps forty or fifty thousand
junks, and vessels of various kinds, arranged
each other in regular rows, with passages be-
hem to allow other vessels to pass. This float-
n extends several miles in length. For what
we know not, the owners of these vessels and
milies are not allowed to come ashore, and so
end the whole of their lives on the water.

Foreigners are not permitted to go ashore and reside at pleasure at Canton. Their only land establishments consist of *hongs* or factories, which extend in a line along the banks of the river, from which they are distant about a hundred yards. They are built on a broad quay, with a spacious promenade in front. The hongs or factories individually consist of courts or lanes, admitting of no thoroughfare, and solely dedicated to the accommodation of the foreign residents. Large warehouses for the reception of goods are adjacent. The place of the Chinese suburbs which is most frequented by foreigners, is termed China Street, consisting entirely of shops, in which the native dealers are to be seen seated from morning till night. Their tricks in entrapping British seamen into purchasing their commodities, have long been matter of notoriety. Their signs uniformly exhibit an English name as well as a Chinese one; and having picked up an acquaintance with the most familiar of Jack's expressions, their mode of addressing their rough customers evinces at once the crafty and unscrupulous disposition of the natives.

The manner in which foreigners have heretofore conducted business at Canton is as follows:—When a ship arrives, it is necessary immediately to get a native merchant (or, as he is called, a hong merchant) to become security for the import and export dues, as well as for the good behaviour of the crew. In this there is never found the slightest difficulty, there being, on the contrary, always a competition amongst the natives for the honour of a consignment. The import duties consist of a tax upon the different species of goods, as well as a tonnage upon the vessel. In addition to the tonnage and cargo charges, there is also levied what is called a *kumshaw*, or present to government, exigible from ships of every burden alike. It has been estimated that all these various port charges, including the expenses of victualling the ships, &c., amount to about 7000 dollars on a ship of 400 tons register.

The foreign merchants at Canton consist of British, American, French, Dutch, Danish, Swedish, Spanish, Portuguese, and Indian British subjects, who in 1832 amounted to 110. There are eight British establishments, seven American, and one joint Dutch and French establishment. Two English newspapers are published in Canton; the Canton Register once a-fortnight, and the Chinese Courier once a-week.

The personal intercourse of Europeans with the Chinese at Canton is chiefly carried on by means of a gibberish (for it cannot be called a language) composed of English, Portuguese, Chinese, and other words, but the whole greatly broken or altered in sound, and possessing no sort of grammatical construction.

At the entrance to an estuary of the river on which Canton is situated, is the island of Macao, containing a town of the same name, part of which forms a settlement or tenancy of the Portuguese, and here also the families of European merchants at Canton have been suffered to reside. The Portuguese privileges have been latterly much circumscribed, and their trade greatly diminished. "From Macao to the Boca Tigris or true entrance of the river [proceeding upwards] is just forty miles, affording a very safe channel for the largest ships. As far as the Boca or Bogue, the whole is a broad estuary of the sea, interspersed with islands, of which the well-known Lintin lies just midway between Macao and the Bogue. Lintin is on the right of the channel for ships, and abreast of it on the left is Lankeet Island, forming behind it the harbour of Kumsing-moon, where the opium ships of late years were accustomed to lie at anchor in safety. There is no entrance to the Canton river to the eastward of the Boca Tigris; but on the west the case is widely different; and it is there that the principal difficulties of a blockading squadron exist. The main part of the river flows through the Bogue; but to the westward there stretches a great delta, which has been gradually formed by depositions of soil from the turbid waters, and is crossed in all directions by shallow channels communicating with each other and with Canton. Some of these channels form the *inner*

absorbed. Then the land air, being below the temperature of the sea air, rushes in to supply its place, and thus during the night, a land-breeze, or a current of air from the land to the sea, is produced. When the sea-breeze first sets in, it commences very near the shore, and gradually extends itself farther out at sea, and, as the day advances, becomes more or less hot. Hence, the sails of ships have been observed quite becalmed six or eight miles out at sea, while at the same time a fresh sea-breeze has been blowing upon the shore. The cause of this is obvious; for it is natural to suppose that the mass of air nearest the land will be the first to rush in, for the purpose of supplying the place of the air which is rarified immediately above it. On this account the effect of the sea-breeze is said not to be perceptible at a distance of more than five or six leagues from the shore, and for the most part becomes fainter in proportion to its distance from land. The distance, on the other hand, to which the land-breeze extends in blowing across the sea, depends on the more or less exposed aspect of the coast from which it proceeds. In some places this breeze was found by Dampier brisk three or four leagues off shore; in other places not so many miles; in others, again, it scarcely extended without the rocks. The sea-breeze, from blowing over a more open tract, is always stronger than the land-breeze; but it is observed that the land-breeze is much colder than the sea-breeze. Furthermore, it has been noticed that the tendency of the land-breeze at night has almost invariably a correspondence with the sea-breeze of the preceding or following day. "Should the land-wind from being east, draw, in the course of the night, towards the north, it would be looked upon," says Marsden, in his *History of Sumatra*, "as an infallible prognostic of a west and north-west wind the next day; and on this principle it is that the natives foretell the direction of the wind, by the noise of the surf at night, which, if heard from the northward, is esteemed the forerunner of a northerly wind, and *vice versa*. The quarter from which the noise is heard depends on the course of the land-wind, which brings the sound with it, and drowns it to leeward; the land-wind has a correspondence with the next day's sea-wind, and thus the divination is accounted for." Unless for the periodical refreshing cool breezes from the sea, the West India islands, and generally all hot countries, would scarcely be habitable for the white races of men.

HURRICANES.

The most dangerous winds to the navigator are those which occur in sudden gusts, or squalls, and for the approach of which the sharpest outlook is required. When the squall is in the form of a violent tempest, accompanied by rain, lightning, and thunder, it receives the name of a hurricane. Hurricanes occur most frequently and with the greatest violence in tropical climates, because, in consequence of the very great heat which there prevails, the rarifaction of the air, and also the condensation of the vapour it contains into rain-drops, take place more suddenly and completely than in more temperate regions. By this means the electricity of the atmosphere—that subtle fluid which seems to pervade all bodies, and which universally seeks its own equilibrium—is disturbed, and no longer maintains an equal distribution through the aërial vapour. It accumulates in vast quantities in one mass of vapour or cloud, while in another it is deficient; and, consequently, to regain its equilibrium, it flashes in the form of lightning from the surcharged cloud, to the cloud that is undercharged, or to the earth itself. Hence, hurricanes are always attended with electrical manifestations, which add greatly to the tragical horrors of the spectacle they exhibit. In describing the tremendous hurricane which took place in the West Indies in 1772, the writer observes, "I must still mention how dreadful every thing looked in this horrible and dark night, *there being* so many fiery meteors in the air, which I, *and others who were in* the same situation, were spectators of. Towards the east, the face of the presented to our view a number of fiery rods— cal brushes—which were through the whol shooting and darting in all directions; likew balls, which flew up and down, here and th burst into a number of small pieces, which, like of flaming straw, came very near the road w lay; yet, notwithstanding all these phenomena, and lightning were abundantly great."

Hurricanes commence in various ways: so from a single and small cloud, which sudd pands, overspreading, as with a dense shroud, t heavens; and sometimes from a slowly gather of clouds which appear to be irradiated with elec When the enterprising navigator, Columbus, w to depart from Isabella Island, while his ves still in the harbour, one of these dreadful hu arose. "About mid-day," says Washington "a furious wind sprang up from the east, drivi it dense volumes of cloud and vapour. Enco another tempest from the west, it appeared violent conflict ensued. The clouds were rent sant flashes or rather streams of lightning. At they were piled up high in the sky, at anot descended to the earth, filling the air with darkness more impenetrable than the obscurity night. Wherever the hurricane passed, who of forests were shivered and stripped of thei and branches, and those of gigantic size which the blast, were torn up by the roots, and hur great distance. Groves were torn from the precipices, and vast masses of earth and roc pitated into the valleys with terrific noise, cho course of the rivers. The fearful sounds in the on the earth—the pealing thunder—the vivid l —the howling of the wind—the crash of falli and rocks—filled every one with affright, an thought that the end of the world was at hand. fled to caverns for safety, for their frail hous blown down, and the air was filled with the tru branches of trees, and even with fragments o carried along by the fury of the tempest. W hurricane reached the harbour, it whirled th round as they lay at anchor, snapped their cabl sunk three of them to the bottom, with all w on board. Others were driven about, dashed each other, and tossed mere wrecks upon the s the swelling surges of the sea, which in some rolled for three or four miles upon the land tempest lasted for three hours. When it had away, and the sun again appeared, the Indians re each other with mute dismay. Never, in their m nor in their traditions, had their island been vis such a tremendous storm. They believed that th had sent this fearful ruin to punish the cruelt crimes of the white men, and declared that this had moved the very air, the water, and the ea disturb their tranquil life, and to desolate their i

The West Indies, the Isle of France, and the doms of Siam and China, are the countries wh most subjected to the ravages of hurricanes. West Indies they most frequently occur in the of August, and the Indians, from their expe originally taught our planters the signs by whic approach may be prognosticated. The hurricane either in the first quarter or at the full change moon. If it come on at the full, then at the pre change the sky looks troubled, and the sun mo than usual; besides which, there is a dead calm and the mountain-tops are free from those mists usually overhang them. In the caverns of the and in wells, a hollow rumbling noise, like a r wind, is heard, and animals are observed to t and be much disturbed. Many animals, indeed, to be very sensible of any change in the electrica of the atmosphere, and indicate their uneasin moaning and great restlessness. At night the seem larger than usual, and are frequently surro with halos. It is said, also, that the sea emits a

he sails were filled; and as the ship gathered way, every erson marked the glistening eye of the helmsman, when he felt the spokes of the wheel pressing against his hand, by the action of the water upon the rudder."

THE ARCTIC SEAS.

The seas within the arctic circle, at the north or outh pole, exhibit appearances so very remarkable, in consequence of the intense cold which there prevails, hat they deserve a particular description. The following vivid sketch of scenes observed within the arctic seas, will be read with interest:—

"After the continued action of the sun has at last melted away the great body of ice, a short and dubious nterval of warmth occurs. In the space of a few weeks, only visited by slanting and enfeebled rays, frost again resumes his tremendous sway. It begins to snow n August, and the snow falls to the depth of two or three feet before October. Along the shores and bays, the fresh water, poured from rivulets or drained from the thawing of former collections of snow, becomes quickly converted into solid ice. As the cold augments, the air deposits its moisture, in the form of a fog, which freezes into a fine gossamer netting, or slender icicles, dispersed through the atmosphere, and so extremely minute, that they seem to pierce and excoriate the skin. The hoar-frost settles profusely, in fantastic clusters, on every prominence. The whole surface of the sea steams like a lime-kiln; an appearance, called the *frost-smoke*, caused, as in other instances of the production of vapours, by the waters being still relatively warmer than the incumbent air. At length the dispersion of the mist, and the consequent clearness of the atmosphere, announce that the upper stratum of the sea itself has become cooled to the same standard; a sheet of ice spreads quickly over the smooth expanse, and often gains the thickness of an inch in a single night. The darkness of a prolonged winter now broods impenetrably over the frozen continent, unless the moon chance at times to obtrude her faint rays, which only discover the horrors and wide desolation of the scene." The wretched settlers, covered with a load of bear-skins, remain crowded and immured in their huts, every chink of which they carefully stop against the piercing external cold, and, cowering about the stove or the lamp, they seek to doze away the tedious night. Their slender stock of provisions, though kept in the same apartment, is often frozen so hard as to require to be cut with a hatchet. The whole of the inside of their hut becomes lined with a thick crust of ice; and if they happen for an instant to open a window, the moisture of the confined air is immediately precipitated in the form of a shower of snow. As the frost continues to penetrate deeper, the rocks are heard at a distance to split with loud explosions. The sleep of death seems to wrap up the scene in utter and oblivious ruin. At length the sun reappears above the horizon; but his languid beams rather betray the wide waste than brighten the prospect. By degrees, however, the further progress of the frost is checked. In the month of May, the famished inmates venture to leave their huts, in quest of fish on the margin of the sea. As the sun acquires elevation, his power is greatly increased. The snow gradually wastes away, the ice dissolves apace, and vast fragments of it detached from the cliffs, and undermined beneath, precipitate themselves on the shores with the noise and crash of thunder. The ocean is now unbound, and its icy dome broken up with tremendous rupture. The enormous fields of ice thus set afloat, are, by the violence of winds and currents, again dissevered and dispersed. Sometimes impelled in opposite directions, they approach, and strike with a mutual shock like the crash of worlds—sufficient, if opposed, to reduce to atoms, in a moment, the proudest monuments of human power. It is impossible to picture a situation more awful than that of the poor crew of a whaler, who see their frail bark thus fatally enclosed, expecting immediate and fatal destruction. Before the end of June, the shoals of ice in the arctic seas are

Where the higher part of either of these great billows strikes our coasts, we have the phenomenon of high water; and when the lower touches us, it is low water. Each of the waves is brought over any given place in the circumference of the earth in twenty-four hours, so as to cause high water twice a-day. The sun is also known to have a certain attractive influence on the waters of the ocean, but from the great distance of that luminary, the effect is comparatively small. But when this minor influence of the sun coincides with that of the moon, or acts in the same way, we perceive a marked increase in the tides; on such occasions we have what are called *spring* or *large* tides. When the solar and lunar attractions act in opposition, we have *neap* or small tides. The spring tides happen twice a month, when the moon is at full and change; and the neap when the moon is in the middle of its orbit between those two points. A tide requires six hours to rise, which it does by small impulses or ripplings of the water on the shore, and six hours to ebb or fall; but every successive high water is from twenty to twenty-seven minutes later than the preceding, or, on an average, about fifty minutes for two tides, in consequence of the earth requiring that time above the twenty-four hours to bring any given point again beneath the moon. The tides are thus retarded by the same reason that the moon rises fifty minutes later every day. It is evident that the tides will be greatest at that point of the earth's surface which is nearest to the moon, or where the latter is vertical. She is so between the tropics; and accordingly the tides are there greatest, and they diminish as we approach either poles. It is further to be remarked, that the moon does not anywhere draw up the tides immediately. Three hours elapse before the waters are raised, in consequence of the law of inertia, or a disposition which every body has to continue in the condition of rest or motion in which it happens to be placed. This stubbornness to resist the moon's influence is only overcome by a three hours' action upon the waters; and thus the tidal wave is always three hours behind the moon in its passage. Twice a-year, namely, in March and September, the tides are higher than at other times, because then the attraction of the sun and moon are strongest. In some of the firths or arms of the sea on the east coast of Scotland, it has been occasionally noticed that there have been four high waters in the twenty-four hours. These, however, are not simple tides. The double risings are caused by the irregular passage of the tidal wave from the Atlantic round the north and south points of the island of Great Britain. When that portion of the wave which proceeds by the south reaches the east coast sooner than that by the north, or vice versa, there will be two risings of the water instead of one. A similar phenomenon may perhaps be observed in other parts of the earth. In the Mediterranean Sea the tides are small, and in some places scarcely perceptible; this is caused by the general confinement of that inland branch of the ocean by the Straits of Gibraltar, which prevent the full action of the tidal wave either in its rising or recession.

CURRENTS.

Besides being affected by the regular motion of the tides, the ocean, in many parts of its extended bounds, is influenced by currents, which act continually in particular directions. Currents are the result of various causes, such as temperature, winds, peculiar construction of coasts and inlets, but chiefly, as is believed, of the rotary motion of the earth. The globe in its diurnal motion leaves, as it were, the fluid behind; and hence there is a perpetual flow of the sea from the western coasts of Europe and Africa towards the eastern *landboard*, as it is called, of America, and from the west of America to the eastern coast of Asia. This movement is chiefly confined to the tropics, unless where the sea is turned aside by the land, and caused to diverge towards the north or south. If we start in a survey of this motion from the western coast of America, we find it producing a constant current across the vast e of the Pacific, till it is turned off by Asia and Au A great division of its force is directed throu seas on both sides of the latter continent, and through the Indian Ocean, and round the Cape o Hope, till it reaches the free expanse of the A across which it proceeds in the same manner as the Pacific. The current of the Atlantic stri coast of Brazil, and breaks at Cape St Augusti two divisions, one of which proceeds round Cap into the Pacific, while the other advances t the Caribbean Sea, and so on into the Gulf of This latter branch conspires, with the vast i fresh waters which pours into the Gulf of Me raise the level of that sea above that of the neig ing ocean, and, causing the surplus to force its between Florida and Cuba, produces the cel Gulf Stream, which is perhaps the most power current in the world.

It is obvious, that to the mariner current be of great importance. From Portugal, for in ships have sailed to the Bights of Benin, Guinea coast, being 150 leagues, in two days, they could not return in less than seven weeks also common for vessels to descend to the lati the Canary Islands, in order to get into the current across the Atlantic, which carries t America in a comparatively short time: it was current that Columbus was carried so smoothl his first voyage to the new continent. The Pa is said, can be crossed in this way in about ten being at the rate of 1000 miles per week; an mariners have expressed an opinion that China be reached by this route in less time than by the course round the Cape of Good Hope.

For the same reason that the sea flows from west, the air has a tendency, when not count by other causes, to move in the same direction earth in its motion leaves the air, like the sea, behind it; in other words, does not carry it so f ward: hence what are called the trade-winds, operating in the same direction with the sea-cu increase the facility of navigation to the westwa very great degree. It is impossible to avoid r ing, that these natural phenomena, which, it i supposed, might have been counteracted or r lised from the beginning, must have been desig some end useful and necessary in the economy world. Perhaps, like the diffusive powers give seeds of certain plants, they were intended to aid dispersion of the human race over the globe. It known that population exists in many places, appear cut off from all connection with others, that must have been impassable by navigators early ages of their art. Men could only be dri such places in early ages by the currents of and air; and thus the cultivation of large and im regions must have commenced much earlier than have otherwise been the case.

Besides the grand equatorial or tropical c there is one of a less decided character from th to the equator. The sea under the tropics eva to a greater extent than elsewhere, by the influ a vertical sun. The vapours are apt to proceed t the north and south, where they descend in ra surplus of water is thus produced in the high la which naturally flows back towards the equator. a constant but comparatively slight flow from th and south towards that warmer region of the Under the influence of this stream, large masse are constantly becoming detached from the polar and drifted to the tropics. In some of the bays north side of Iceland, this frigid substance co vast quantities, insomuch as to choke them up depth of 500 feet. What is still more strange, masses of ice are sometimes mixed up with trees of which are known to be the produce of the zone in America: this is accounted for by the ac the northern division of the great current which

ARITIME DISCOVERY—NAVIGATION.

vigation is the art of conducting vessels at sea in irection in which they are designed to proceed; rm is derived from the Latin words *navis*, a ship, go, to manage or govern. From *navis* also is d the term *navy*, which signifies a collection of The terms *marine*, *maritime*, and *mariner*, are se from a Latin root, to wit, *mare*, the sea.

the early history of ship architecture and naviga- little can be said of any importance. The buoyant rty of water, particularly that of the sea, must have oon observed by mankind, and therefore beginning ude skiffs and canoes, they would in time acquire ent experience and skill to construct vessels of a r size, and to guide them in the required direction ans of a rudder and sails. The cultivated nations tiquity, Egyptians, Carthaginians, Phœnicians, thers, living on the shores of the Mediterranean, ed ships both for commerce and war, some of were of a large size, and moved by rowers, and acting on the sails. But no people of antiquity ssed the courage or skill to navigate their vessels sight of land, or, at least, to push into the open At- or other great oceans. Maritime intercourse, for ke of traffic, was carried on only along the shores Mediterranean, or down the Red Sea, and along ast to India, or along the western shore of Europe itain. The Romans thought they performed a rfully bold feat when they sailed a ship as far as rthern islands of Scotland. In those times there o other known guide, with respect to the cardinal , than the stars by night and the sun by day; herefore, when clouds covered the visible horizon, m total darkness ensued at night, the ship was arily brought to a pause, or placed in the most nent danger of being wrecked on some unknown . This, however, was not the only difficulty. The s of antiquity, with all their learning, were utterly ant of the form and size of the globe. They believed he world was a great flat plain, with the habitable placed in the midst of the ocean; that this ocean f interminable breadth; and that, at a certain ce from land, the waters were shrouded in eternal ess. With such notions prevailing among mankind ousands of years, it is not surprising that they l have made so slow advances in the art of navi- , or done so little for maritime discovery.

ring the middle ages (fourth to the fourteenth ry), ship-building was considerably improved by talians, who then conducted a large maritime on the Mediterranean; but the art of navigation, proper sense of the term, was still in its infancy, s history cannot be said to commence till the ning of the fourteenth century, when that wonder- strument, the mariner's compass, was discovered, ne first into observation in Europe. Of the polarity magnet, or its tendency to point to the poles, a ent explanation will be given in the article Elec- y and Magnetism; and it is here only neces- o describe how this polarity is rendered subser- to the purposes of the navigator. The mariner's ss, which consists of a magnetised slip of metal, dle, as it is called, poised on its centre, and free to to the poles, was first made known, as far as it can ertained, by one Flavio Gioja, an Italian, in the 302. As with all great discoveries, its advantages not at once recognised—it had to contend against ety of prejudices; but these in time vanished, and the middle of the fourteenth century its impor- ses were allowed and established.

vigation now assumed a much bolder character formerly. The English, Portuguese, Italians, and ards, pushed their vessels into districts of ocean previously traversed, and thus the way was fairly d for maritime discovery. The first great dis- er who made use of the compass, and partly ved its construction, was Prince Henry, a son of

the King of Portugal, and who is known in history by the name of *Henry the Navigator*. This intelligent and enterprising prince (born 1394, died 1461), with the concurrence of the Portuguese government, set on foot a series of maritime enterprises, with the view of discovering a route to India by way of the Atlantic. These voyages ultimately proved successful; the islands of Puerto Santo, Madeira, and the Canaries, were successively discovered, and annexed to the crown of Portugal. In 1433, the Portuguese navigators penetrated beyond Cape Bojador, on the coast of Africa, which was considered an extraordinary performance; another expedition afterwards went as far as Cape Blanco, and discovered the Island of Arguin and the Cape de Verde Isles; and in 1448, the Azores were reached and made known. Henry the Navigator thus struck a spark which kindled to a flame all over Europe. Not long after his death, the Guinea coast was added to the Portuguese discoveries. In 1484, the Congo was reached by Diego Cam; in 1487, the Cape of Good Hope was doubled by Bartholomew Diaz; and in 1498, Vasco de Gama touched the shores of Hindostan. The Portuguese having received an assignment from the pope of all lands that could be discovered on the African coasts, the Spanish government, burning with anxiety to emulate the late proceedings of its neighbours, was compelled to seek out new countries in a different direction. Ferdinand and Isabella, the sovereigns of Spain, listened, therefore, to the speculations of Columbus regarding a route to India across the Atlantic, and sent him off on a mission. In this his bold attempt to reach Hindostan by pursuing a direction across the Atlantic, he landed on one of the American islands, now called the Bahamas, on the 12th of October 1492. About the year 1499, Amerigo Vespuccii, under an appointment from the Spanish government, discovered the coast of the South American continent, and hence the name of *America* was given to the New World, although, as is well known, Columbus had previously discovered and landed on South America, without being aware that it was the continent which he had reached.

Several subsequent voyages by Spanish navigators disclosed the extent of the east coast of South America, and in 1513, Nunez de Balboa crossed the isthmus of Panama with an exploring party of his sailors, and made the discovery of the Pacific Ocean on the west coast of that continent. It was now seen that America was not, as had been at first believed, a portion of Asia or India, but was a separate territory of vast extent lying between the Atlantic and Pacific. There was yet a doubt with respect to the southern extremity of America, but in 1520, Magellan made the passage from the Atlantic to the Pacific by the straits which separate America from the island of Terra del Fuego, at about the 53d degree of south latitude, and so removed all doubt upon the subject. This navigator extended his voyage across the Pacific to the Philippine islands, where, unfortunately, he was killed; but his companions proceeded in the route homewards by the Cape of Good Hope, and thus, by circumnavigating the globe, settled the long-disputed problem with respect to the sphericity of our planet. This most important voyage was made between the years 1520 and 1523.

In the meanwhile, several maritime discoveries were made by the English nation. In 1495, John Cabot, a Venetian pilot, settled at Bristol, obtained from Henry VII. letters patent, empowering him and his three sons, Lewis, Sebastian, and Sanctius, to discover unknown lands, and conquer and settle them. In consequence of this permission, the king supplied one ship, and the merchants of London and Bristol a few smaller ones, and in 1496, John and Sebastian sailed to the north-west. In July of the same year, they discovered Newfoundland, and explored it up to latitude 67°. In a subsequent voyage, the father and son sailed as far as Cape *Florida, and are believed* to have been the first who *saw the mainland of America*. By these and succeeding *voyages of discovery* in the reigns of Henry VIII., *Edward VI., and Elizabeth*, the English became possessed of the eastern coast of North America, and of its islands. Between the years 1740 and 1744, A was employed in circumnavigating the globe, and ing different parts of the Pacific, but this extensiv protracted voyage added little to the existing know of geography. At a later period, in the reign of G III., Cook explored the groups of islands in the P making various interesting discoveries, in whic included a survey of the eastern coasts of Austral Van Dieman's Land, also a visit to the New Z islands. After the voyages of this enterprising gator, little was left to perform in the way of ma discovery, except in exploring the northern extre of the American continent. A series of voyag this purpose was begun in 1818, conducted by Parry, and others, and which lately terminated h blishing the fact, that a passage for ships exists be the Atlantic and Pacific, round the northern pr tories of America, but that, from the blocking such a passage can only on rare occasions be o navigators, and is therefore of no practical value.

INSTRUMENTS OF NAVIGATION.

The great maritime discoveries made in the of the fifteenth century, which at once opened new view of the globe, led to various improveme navigation. The *log*, for measuring the ship's pro also charts on Mercator's projection, were introd In 1614, Napier discovered the calculation of num quantities by logarithms; and about the year Gunter invented a scale, by the help of which, pair of compasses, every question in trigonometry easily be calculated by the mariner. In 1731, t of navigation was greatly advanced by the inve or rather improvement, by Hadley, of the qua an instrument for ascertaining, by an observation sun, the true latitude of a ship at sea. Till nearl period, an instrument called an *astrolabe*, a spec sun ring, had been employed for this purpose, an very imperfect in its operation. Between the 1765 and 1774, Harrison invented a chronomete time measurer, by which the longitude could be a tained at sea with nearly perfect accuracy; and the art of navigation may be said to have been pleted. In the course of the eighteenth century true figure of the earth was fully made known b voyages of Anson, Cook, and others; and, at the time, discoveries were made of almost every acce island and tract of land over the globe. Thus, i short space of four centuries from the time whe first impulse was given by the Portuguese, the civ part of mankind had acquired a nearly complete k ledge of the features of our globe, as well as of its figure and dimensions.

THE COMPASS.

The most important instrument for the guidan the mariner is the compass. There are different of compasses, to suit peculiar purposes; but that w is commonly in use on shipboard is of the follo construction. The most essential part is a magne bar of steel, called the needle, which is supported zontally on a central pivot, round which it is free to and to point in any direction. The pivot of the n rises from a circular *card*, resembling the dial-pl

d allow it to haul in easily. Then, having gathered sufficient quantity of line into his hand, he throws it r to leeward, that it may not be affected by the eddies ich follow in the wake. The stray line, which allows e chip to get astern, now runs off, and the instant at the white rag, which marks its termination, passes rough the hand of the officer, he cries, "Turn!" and ntinues to veer out line until the glass runs out, and e person holding it cries "Stop!" Then the line is asped, and the number of knots that have passed off ark the speed of the ship. When this exceeds five ots, it is usual to use a glass of 15 instead of 30", unting the knots double. The rate of sailing, per ur, multiplied by the hours sailed, thus gives the ariner the measure of his run.

In addition to these essential instruments for directg the course and ascertaining the distance, the navitor must be provided with octants of double reflection, measure the altitude of the heavenly bodies, and a rcle, or sextant, more nicely graduated, to measure stances between the moon and stars. He should also ve with him a book containing the logarithms of mbers, sines, tangents, and secants, to facilitate trinometrical calculations; tables for correcting altides for dip, parallax, and refraction; also lists of titudes and longitudes for every part of the world; d of time of high water at every port, at the period full and change of the moon, from which, at all times, be able to find the tide; and a variety of tables, to cilitate the various problems of navigation. He should so have with him the Nautical Almanack, containg the places and declinations of the fixed stars and anets, and especially the distances of the moon from e sun and other stars, and all that relates to that ly, with a view to calculate the longitude by observation. Finally, he must be provided with the general d local charts applicable to his contemplated voyage. hus furnished, the mariner may set sail with confince; many do so with no other aids than their mpass, log, quadrant, a single chart, and book of vigation, and arrive in safety. But it is less our siness to show with how little care a ship may be vigated, than to show how she may be carried from rt to port with the greatest possible certainty. Havg taken leave of the port, and, when the last land is out to disappear from view, either from the growing stance or the intervention of night, the mariner selects me conspicuous headland, of which the latitude and ngitude are noted in his tables, and, placing a comss in some elevated position, remote from any iron ject to disturb its polarity, proceeds to determine its aring, and estimate his distance from it, either by e progress made from it, or by the ready estimate of practised eye. Or, taking the simultaneous bearings two distinct points of coast, he has still surer data r deducing his position. This is called *taking the eparture*, and is carefully noted on the log-slate, with e time of making the observation. Thenceforth the g is thrown every hour, and the course and distance re entered upon the slate, to be copied into the logook at the end of the day. The first thing which the vigator attends to, after making the offing which rudence dictates to clear the dangers of the land, is to hape his course for the port of his destination. And rst he searches in the chart if there be any point of nd, island, or rock, intervening in his way. If there e, the course is primarily shaped with reference to the anger; if not, the differences of latitude and longitude etween the two places being taken, the course and istance are obtained by the aid of trigonometry. The hortest distance between any two places on the surface f our sphere, is the arc of a great circle passing through hose two places. Thus, between Cape Henry, in latiude 37°, and the Island of St Mary in the same latitude, ut 50° longitude farther east, the distance is 30 miles ss in sailing on a great circle, than if you were to sail lue east on a parallel of latitude, and consequently on lesser circle of the sphere. In a higher latitude, the difference between sailing on a great or small circle

The extraordinary part which *animals* play in colouring the ocean, may be demonstrated by alluding to the vast tracts of the northern sea, which among mariners are familiarly known as *green water*, and which do not, under any circumstances, assume a blue tint. Mr Scoresby thus describes them:—"After a long run through water of the common blue colour, the sea became green and less transparent. The colour was nearly grass-green, with a shade of black. Sometimes the transition between the green and blue water is progressive, passing through the intermediate shades in the space of ten or twelve miles; at others, it is so sudden that the line of separation is seen like the ripple of a current, and the two qualities of water keep apparently as distinct as the waters of a large muddy river on first entering the sea. In 1817, I fell in with such narrow stripes of various coloured water, that we passed streams of pale green, olive green, and transparent blue, in the course of ten minutes' sailing."* These green regions extend for tens of thousands of miles, and it has been distinctly proved that the peculiar colour is produced by inconceivable multitudes of microscopic animals, principally minute sea blubber, *medusæ*, and *infusoria*. Some of these animals are green, and directly produce the colour which is exhibited, but many more are yellow, which colour, combining with the blue of the sea water, will also, as every one knows, produce a green tint.

Other appearances, proceeding from a similar cause, and, if possible, still more striking, are also witnessed. Thus, a *red colour*, sometimes characterised as blood or carmine red, frequently astonishes the voyager. The water of the Gulf of California in the Northern Pacific is reddish, whence it is sometimes named the Vermilion Sea.† Captain Colnet, in the interesting account of his voyage, states—"That the set of the currents on the coasts of Chili may at all times be discovered by noticing the direction of the beds of small blubber with which the coast abounds, and from which the water derives a colour like that of blood. I have often been engaged," he adds, "for a whole day in passing through various sets of them." The celebrated naturalist D'Orbigny makes similar remarks concerning the waters of the Atlantic. "There are immense tracts," says he, "off the coasts of Brazil, filled with small animals so numerous as to impart a red colour to the sea; large portions are thus highly coloured, and receive from the sailors the name of the Brazil Bank. This bank extends over a great part of the coast of that country, keeping at nearly the same distance from the shore. Another bank of the same sort occurs near Cape Horn, in latitude 57 degrees. Captain Cook, in his third voyage, encountered the same appearances, and states, "that on examination the phenomenon was found to proceed from an infinity of little animals which, when viewed by the microscope, had the shape of cray fish of a red colour." Hence we are not to wonder, that, according to an intelligent mariner, "the southern seas sometimes presented an appearance which terrified their early navigators, who, seeing large spaces of the sea of a blood-red colour, conceived it a portent of some dreadful catastrophe." These singular appearances are not, however, confined to southern regions. At all events, Mr Scoresby narrates, that he noticed in his last voyage, in 1823, some insulated patches of *reddish-brown* water, which were found to be occasioned by animalculæ; and often, too, were the icebergs and snows tinged with an *orange-yellow* stain. "The animal," he adds, "which gives this peculiar colour to the sea, is about the size of a pin's head, transparent, and marked with twelve distinct patches of a brownish colour." The same appearances have not unfrequently been noticed in fresh water; and, under the name of *blood-rain*, have sometimes caused no small alarm over wide districts. We must not on this occasion attempt to account for all these appearances, but may note, that M. Ehrenberg, in the steppes of Siberia, examined some of these waters. "In a fen," he remarks, "with a pool of water, th red blood colour was very striking, even at a d This colour, I found on examination, was con the slimy surface, which in different places fo shining skin. The red colour was darkest up t of the marsh. M. Chantran, in the year 1797, ex in France a pond which exhibited the same appea the water being of a brilliant red colour, with between cinnaber and carmine; as did Weber many, near Halle, in 1790. In all these latter in the colour was produced by infusory animals. *white* is another colour which is not unfrequent tioned. Thus Captain Tuckey states, that, ne Palmas, upon the coast of Guinea, his vessel a to move in milk, which circumstance arose fr multitude of animals upon the surface which ol the natural colour of the liquid. And once m existence of a *yellow-coloured* sea from the sam is satisfactorily established. "In approaching th point of America," says Captain Colnet, "we th noon passed several fields of spawn, which cau water to bear the appearance of barley, cover surface of a bank."

These causes of varied colour in the ocean, h striking in themselves, are not likely to misle one as to the inherent colour of its waters. It rent, however, with the class of causes to which proceed, and which we may arrange under the *the reflection of coloured rays* from the *bed or be the sea*. Sometimes, indeed, though rarely, th pearances are quite as singular as any we have considered. Thus, in the Bay of Loango, the are almost always of a deep red colour; so m that they are said to be mixed with blood, and Tuckey satisfied himself that the bottom is in red. Let us substitute for this bright red bott of the same shade, but obscure and slightly re and the water of the Bay of Loango would then of an *orange-yellow* colour. Far more frequentl ever, the bed of the sea is of a yellow rather tha hue; and if this colour is at all bright and stro slight blue of the pure water will scarcely affect then the waters will appear *yellow*—a tint whic be observed, is in fact by no means uncommon o sea-shores. But *bright yellow* is by no means mon a tint of sea-sand as is *dull* or *obscure yello* this, owing both to its own proper colour, and its being obscured by a great mass of superi water. When the yellow hue is thus reduced, th ray reflected from the bottom, mixing with the p of the ocean, produces, as is universally known, tint, which is communicated to the water; and one of the most widely spread modifying ca change in the proper colour of the sea.

But the most difficult part of the problem s mains; and that is, to account for the green co the ocean in those places where it is hundre thousands of fathoms deep, and where, of course, thing like reflection from the bottom is quite out question. M. Arago, to account for the phen occurring under such circumstances, offers a which resolves itself into the principle, that wh surface is troubled, the luminous rays, coming fr waves to the eye, consist more of *transmitted* ra of *reflected* rays, and therefore are green. Ac to this view, the appearances exhibit themselv during a breeze which disturbs the surface, the midst of a swell, so common over the ocean. observer stands upon the deck of the vessel, the often overtopping the level of the ship; the lu rays which reach the eye from the sea must have from the distant horizon through one or more watery ridges; thus the transmitted rays have minated over the reflected ones, and so, accord the allowed fact, must be green.

WINDS—TRADE-WINDS.

nd to make ready for the storm, when in former
the dreadful visitation would have fallen upon
unprepared. The marine barometer has not been
neral use for many years, and the author was one
numerous crew who probably owed their preser-
n to its almost miraculous warning. It was in a
hern latitude. The sun had just set with placid
urance, closing a beautiful afternoon, and the usual
h of the evening watch was proceeding, when the
ain's order came to prepare with all haste for a
. The barometer had begun to fall with appalling
dity. As yet, the oldest sailors had not perceived
a threatening in the sky, and were surprised at
extent and hurry of the preparations: but the
ired measures were not completed, when a more
l hurricane burst upon them than the most expe-
ced had ever braved. Nothing could withstand it;
sails, already furled and closely bound to the yards,
riven away in tatters: even the bare yards and
s were in great part disabled; and at one time the
le rigging had nearly fallen by the board. Such,
few hours, was the mingled roar of the hurricane
e, of the waves around, and of the incessant peals
hunder, that no human voice could be heard, and
let the general consternation even the trumpet
ded in vain. In that awful night, but for the little
of mercury which had given the warning, neither
strength of the noble ship, nor the skill and energies
he commander, could have saved one man to tell
tale. On the following morning the wind was again
est, but the ship lay upon the yet heaving waves,
unsightly wreck."

journal of events and observations on board ship
usually kept in what is called the log-board, and
eferred thence into the log-book. The log-board
sists of two boards shutting together like a book,
divided into several columns, containing the hours
he day and night, the direction of the winds, and
course of the ship, with all the material occurrences
happen during the twenty-four hours, or from noon
noon, together with the latitude of observation. From
table, which is written in chalk and daily effaced,
officers work the ship's way, and compile their
rnals. From it, also, entries are carried to the
book, in an expanded form, with any observations
additional particulars supposed to be necessary.
log-book is thus the journal of the ship, and is
served with great care for exhibition, if required,
he termination of the voyage.

hus, then, by the use of various instruments and
ctical experience in navigation, a ship is conducted
n port to port, dangers avoided and difficulties over-
e. Though they who traverse the vast ocean leave
track for the guidance of those who follow, it is thus
verted into a plain and convenient highway, extend-
to the extremities of the earth.

SAILING.

t is important that young men, in acquiring in-
ction in navigation, should also make themselves
uainted with the laws of fluid and atmospheric
on. These are treated of in other parts of the
sent work, and need here be only alluded to in a
eral way in reference to the sailing of vessels.

A ship at sea depends principally on the winds as a
ans of impulsion to its destined port. In moving
ough the water, it encounters a certain resistance
ich must be overcome by the pressure on the sails.
e degree of this resistance depends on the shape of
vessel, and also on the degree of speed to which the
sel is urged in its course. Of the proper shape of
vessel to give the least possible resistance, we have
best of all examples in those which nature has pro-
ted to our observation in the form of the duck and
er water-fowl, and also in the trout, haddock, salmon,
d various other kinds of fish. In all these natural
dels, the form is that of a wedge with the broad end
emost, leaving the narrow tapering end behind to
ow the displaced fluid to disperse itself freely. These

becomes more considerable, as the small circles grow smaller; thus, in the latitude of 60°, a distance equal to that between Cape Henry and St Mary would offer a disparity of nearly 200 miles. But as it is only in sailing on the equator, or on a meridian, that the compass points us uniformly along a great circle of the sphere, in most cases it would be necessary to change the course at short intervals, in order to attain even an approximation towards this desideratum.

WORKING A RECKONING.

At the first noon succeeding the time of taking his departure, the mariner works up his reckoning. Noon is an epoch fixed by nature, being determined by the passage of the sun over the meridian, and is therefore well chosen as the beginning of the day. The log-slate being marked, he copies the courses and distances, if from head-winds or other cause they have been various; the departure from the land is also converted into a course; as is also the current, if there be any known one. He next proceeds to find the difference of latitude and departure from the meridian corresponding to each course, either by geometrical calculation, or, more expeditiously, by reference to tables; then he adds the several differences of latitude and departure, and, if they be of different names, as some north and some south, some east and others west, deducts the less from the greater. With the remaining difference of latitude and departure, he not only finds the course and distance made good, but also the latitude and longitude in; the difference of latitude being applied to the latitude left, by adding or subtracting, in sailing from or towards the equator, at once gives the latitude of the ship. But before the departure can be thus applied to find the longitude, it is necessary to reduce it for the converging of the meridians towards the poles; for, though all degrees of longitude are divided, like those of latitude, into 60 minutes or miles, yet they decrease in length, from being equal to a degree of latitude at the equator, until they become nothing at the poles. There are many ways, more or less accurate, of deducing the difference of longitude from the departure, the latitude being known; they are founded upon this principle: the circumference of the earth at the equator is to its circumference at any given parallel of latitude, as the departure is to the difference of longitude. The most easy and correct way of obtaining the difference of longitude, on an oblique course, is by the aid of a table of meridional parts; for, having taken out the meridional difference of latitude, the mariner has this simple proportion: the proper difference of latitude is to the meridional difference of latitude, as the departure to the difference of longitude. The difference of longitude thus obtained, is applied to the longitude left, adding or subtracting, in sailing to or from the first meridian, and the result will be the ship's longitude; which, with the latitude previously ascertained, determines her position on the chart. The method of navigating thus described is called *dead reckoning*. It is far from infallible, and leaves much to desire. It will, indeed, do pretty well in short runs; but as errors daily creep in from many causes escaping calculation, such as bad steerage, leeway, heave of the sea, unknown currents, and as these accumulate, and become considerable at the end of a long voyage, it becomes necessary for the mariner, removed from all reference to terrestrial objects, to resort to the immoveable guides in the heavens, whose motions the God that placed them there has given him capacity to comprehend. Let us now see how the ship's position on the ocean, represented by latitude and longitude, may at any time, without reference to course sailed, or distance, to capricious winds and stealthy currents, be ascertained with ease and accuracy. And, in the first place, to find the latitude, we have abundant data. All the heavenly bodies are, by the revolution of the earth, daily brought to the meridian, at which time, if their altitude be measured, *their declination* or distance from the equinox being *known, the latitude* is readily deduced; it may also be deduced from single or double altitudes of bodies not in the meridian, the times being accurately known. But the meridian altitude of the sun is what furnishes at once the easiest and most correct method of finding the latitude. The meridian altitudes of the stars, and frequently of the moon, must be taken at night, when the horizon is vaguely marked; moreover, their minuteness and want of brilliancy make observation troublesome and uncertain; but when the sun comes to the meridian, the observer brings a brilliant and palpable object down to a well-defined horizon; then, too, he has the advantage of observing, at a half-fixed epoch, the beginning of a new day. So great, indeed, are the advantages offered by the meridian altitude of the sun, that no other means of finding the latitude are used, except when these have failed from a clouded atmosphere, or when the momentary expectation of making the land quickens the mariner's anxiety. We shall, therefore, now explain the method of deducing the latitude from the sun's meridian altitude.

TAKING AN OBSERVATION.

Furnished with a sextant, circle, or octant of reflection, the observer goes upon deck, and, having examined the adjustment of his instrument, proceeds to bring down the image of the sun reflected by its mirror, until the lower limb just sweeps the horizon. He continues to follow and measure its ascent, until it ceases to rise; the moment that it begins to fall, and the lower limb dips in the horizon, the sun has passed the meridian. The altitude marked by the index being read off, it is next corrected. And first, the observer adds the semi-diameter, in order to make the altitude apply to the centre of the object; next, he subtracts the dip, to meet the error caused by the extension of the horizon, in consequence of the rotundity of the earth, and the elevation of his eye above its surface; also the refraction of the atmosphere, by which the object, when not vertical, is made to appear higher than its true place; lastly, he adds the parallax (a small correction, inconsiderable from the sun's distance), in order to reduce the calculation for the centre of the earth; from which point all calculations are made, and which is ever supposed to be the station of an observer. Having made all these corrections, which many mariners dispatch summarily, by an addition of 12 minutes, he has the true meridian altitude of the sun. Taking this from a quadrant, or 90°, gives its zenith distance, or distance from that point in the heavens which is immediately over the observer, and would be met by a straight line passing from the centre of the earth through his position. Now, if the sun were for ever on the equinoctial, the zenith distance would always be the latitude; for, whilst the zenith is the observer's position, referred to the heavens, the equator is there, in like manner, represented by the equinoctial; and we have already seen that latitude is the distance from the equator. But as the sun is only twice a-year upon the equinoctial, and as his distance from it at times increases to more than 20°, it becomes necessary to take this distance (called his *declination*) into the estimate. The sun's declination is given in the Almanack, for the noon of each day; by correcting it for the time anticipated or elapsed, according as the sun comes first to him or to the first meridian, by his position east or west of east of it, the observer obtains the declination for noon at his own position. This declination applied to the zenith distance, by adding when the sun is on the same side of the equator, by subtracting when on the opposite side, gives the true latitude. A daily and accurate knowledge of his latitude is, then, to the mariner of our day, a desideratum of easy attainment. By its aid, nothing is easier than to sail clear of any rock or shoal that crosses his track, either by a watchful look-out at the moment of passing its latitude, or else by avoiding its parallel entirely, until it be surely passed. Moreover, this is his best and surest guide in aiming at his destined port; for he has but to attain the exact latitude it lies in, and then sail directly upon it, east or

and to make ready for the storm, when in former
as the dreadful visitation would have fallen upon
unprepared. The marine barometer has not been
general use for many years, and the author was one
a numerous crew who probably owed their preser-
ion to its almost miraculous warning. It was in a
thern latitude. The sun had just set with placid
earance, closing a beautiful afternoon, and the usual
th of the evening watch was proceeding, when the
tain's order came to prepare with all haste for a
m. The barometer had begun to fall with appalling
bility. As yet, the oldest sailors had not perceived
n a threatening in the sky, and were surprised at
extent and hurry of the preparations: but the
uired measures were not completed, when a more
ful hurricane burst upon them than the most expe-
nced had ever braved. Nothing could withstand it;
sails, already furled and closely bound to the yards,
re riven away in tatters: even the bare yards and
sts were in great part disabled; and at one time the
ole rigging had nearly fallen by the board. Such,
a few hours, was the mingled roar of the hurricane
ve, of the waves around, and of the incessant peals
thunder, that no human voice could be heard, and
dst the general consternation even the trumpet
nded in vain. In that awful night, but for the little
e of mercury which had given the warning, neither
strength of the noble ship, nor the skill and energies
the commander, could have saved one man to tell
tale. On the following morning the wind was again
rest, but the ship lay upon the yet heaving waves,
unsightly wreck."

A journal of events and observations on board ship
usually kept in what is called the log-board, and
nsferred thence into the log-book. The log-board
nsists of two boards shutting together like a book,
d divided into several columns, containing the hours
the day and night, the direction of the winds, and
course of the ship, with all the material occurrences
at happen during the twenty-four hours, or from noon
noon, together with the latitude of observation. From
is table, which is written in chalk and daily effaced,
officers work the ship's way, and compile their
urnals. From it, also, entries are carried to the
g-book, in an expanded form, with any observations
d additional particulars supposed to be necessary.
e log-book is thus the journal of the ship, and is
eserved with great care for exhibition, if required,
the termination of the voyage.

Thus, then, by the use of various instruments and
actical experience in navigation, a ship is conducted
om port to port, dangers avoided and difficulties over-
me. Though they who traverse the vast ocean leave
track for the guidance of those who follow, it is thus
nverted into a plain and convenient highway, extend-
g to the extremities of the earth.

SAILING.

It is important that young men, in acquiring in-
ruction in navigation, should also make themselves
quainted with the laws of fluid and atmospheric
tion. These are treated of in other parts of the
esent work, and need here be only alluded to in a
neral way in reference to the sailing of vessels.

A ship at sea depends principally on the winds as a
eans of impulsion to its destined port. In moving
rough the water, it encounters a certain resistance
hich must be overcome by the pressure on the sails.
he degree of this resistance depends on the shape of
e vessel, and also on the degree of speed to which the
ssel is urged in its course. Of the proper shape of
e vessel to give the least possible resistance, we have
e best of all examples in those which nature has pre-
nted to our observation in the form of the duck and
ther water-fowl, and also in the trout, haddock, salmon,
nd various other kinds of fish. In all these natural
odels, the form is that of a wedge with the broad end
rmost, leaving the narrow tapering end behind to
llow the displaced fluid to disperse itself freely. These

it is of less importance to have sharp bows to cleave the water, than to have a *fine run* or gradual taper from bows to stern. Of this peculiarity of construction we shall hereafter speak in the article SHIPS; our object at present is chiefly to notice the principle of resistance in relation to the speed. According to the laws of liquids, *the resistance presented by the water increases as the square of the speed*, that is, the resistance is four times greater with only a double rate of speed. This law of fluid action is simply and beautifully explained by Dr Arnot. "A boat which moves one mile per hour, displaces a certain quantity of water, and with a certain velocity; if it move twice as fast, it of course displaces twice as many particles in the same time, and requires to be moved by twice the force on that account; but it also displaces every particle with a double velocity, and requires another doubling of the power on this account: the power thus being doubled on two accounts, becomes a power of four. In the same manner, with a speed of three, three times as many particles are moved, and each particle with three times the velocity; therefore, to overcome the resistance, a force of nine is wanted; for a speed of four, a power of sixteen; for a speed of five, a power of twenty-five, and so forth. Thus, even if the resistance at the bow [fore part] of a vessel were all that had to be considered, the force of 100 horses would only drag the vessel ten times as fast as the force of one horse. But there is another important element in the calculation, namely, the lessening, as the speed quickens, of the usual water pressure on the stern [hind part], which pressure, while she is at rest, is equal to the pressure on the bow; and the force, therefore, required to produce an increased velocity is still considerably greater than that noted. There is not a more important truth in physics than the law of fluid resistance to moving bodies, here treated of; it explains so many phenomena of nature, and becomes a guide in so many matters of art.

We shall now (continues the Doctor) set forth some interesting examples. It explains at what a heavy expense of coal high velocities are obtained in steam-boats. If an engine of about 50 horse power would drive a boat 7 miles an hour, two engines of 50, or one of 100, would be required to drive it 10 miles, and three such to drive it 12 miles; even supposing the increased resistance at the bow, as already stated, to be the measure of the whole work done, which it is not, and that engines work to the same advantage with a high velocity as with a low, which they do not. For the same reasons, if all the coal which a ship could conveniently carry were just sufficient to drive her 1000 miles, at the rate of 12 miles per hour, it would drive her much more than 3000 at a rate of 7 miles per hour; and much more than 6000 at a rate of 5 miles per hour. This is a very important consideration for persons concerned in steam navigation to distant parts.

The same law shows the folly of putting very large sails on a ship; the trifling advantage in point of speed by no means compensating for the additional expense of making and working the sails, and the risk of accidents in bad weather. The ships of the prudent Chinese have not, for the same tonnage, one-third so much sail as those of Europeans, and yet they move but a little slower on that account. A European ship under jury-masts does not lose so much of her usual speed as most people would expect.

This law explains also why a ship glides through the water 1 or 2 miles an hour when there is very little wind, although with a strong breeze she would only sail at the rate of 8 or 10 miles. Less than the 100th part of that force of wind which drives her 10 miles an hour, will drive her 1 mile per hour, and less than the 400th part will drive her half a mile. Thus, also, during a calm, a few men pulling in a boat can move a large ship at a sensible rate.

These considerations show strikingly of what importance to navigation it might be to have, as a part of a *ship's* ordinary equipment, one or two water-wheels, to *be affixed upon the ship's side when required*, like the paddle-wheels of a steam-boat, and by turning [illegible] crew might deliver themselves from the tedium [illegible] disastrous consequences, of a long calm at sea.

The impulse which a vessel at sea receives [illegible] wind, is generally of greater value when given [illegible] degree sideways, than when direct on the [illegible] least it is so when there are several masts. The reason of this is very obvious: when the [illegible] directly astern, it can only affect one or [illegible] sails with any commensurate force; but when [illegible] slantingly on the vessel in the direction of [illegible] every sail in the ship may be trimmed to [illegible] breeze, and so all receiving an equally powerful [illegible] a corresponding effect is produced. It is [illegible] prime arts in seamanship so to trim or arrange [illegible] sails of a vessel, as to take advantage of a wind [illegible] is almost right ahead. This is called sailing close [illegible] wind. Some vessels, by tacking, or sailing in a zigzag [illegible] direction, can be made to proceed within a few [illegible] points of the wind, and thus are always gaining [illegible] little in their course, while others, less [illegible] rigged and managed, would be compelled to [illegible] stop. Dr Arnot suggests a method by which [illegible] might be made to steer, that is, guide, [illegible] through the ocean, particularly in cases of [illegible]

"It is possible to make a ship or boat steer [illegible] placing a powerful vane on the mast-head, [illegible] necting it with the tiller-ropes by two projec[illegible] from its axis. If it were desired to make the [illegible] directly before the wind, the tiller-ropes would [illegible] to the vane, so that the helm should be in [illegible] position when the vane were pointing directly [illegible] should the vessel, then, from any cause devi[illegible] her course, the vane, by its changed posi[illegible] respect to her, would have produced a corr[illegible] change on the position of the helm, and just [illegible] bring her back to her course. Again, it is evi[illegible] by adjusting such a vane and rudder to each [illegible] different ways, any other desired course [illegible] obtained, and which would alter only with [illegible] The vane would require to be of large size to [illegible] necessary power; a wide hoop, for instance, [illegible] vass stretched upon it; and the rudder, that [illegible] turn with little force, would be hung on an ax[illegible] through its middle, instead of, as usual, by [illegible] one edge. Cases have occurred where ship[illegible] persons might have sent intelligence of their [illegible] to a distant coast by a small vessel, or even [illegible] wood fitted up in this way; and the meth[illegible] sometimes save an additional hand in a boat's [illegible]

DOMINION OF THE SEAS.

It is a common law of nations that the ocean [illegible] and universal highway, which no state can ap[illegible] to its own especial use. While this exists a [illegible] ciple generally recognised by all civilised powe[illegible] Britain has for a considerable period of time [illegible] *the dominion of the seas*, as a right acquire[illegible] extensive conquests, and the skill and valo[illegible] seamen. By this claim, it is not assumed th[illegible] Britain possesses a legal right of property in th[illegible] of the ocean, or the lands which they may cov[illegible] claim resolves itself into what is termed [illegible] military sovereignty," which it would be ex[illegible] difficult to define, and is practically an empty [illegible] glorious boast. Within the last twenty years [illegible] which a large maritime force has grown up in [illegible] Russia, and the United States of America, the [illegible] the British to the dominion of the seas has b[illegible] heard of, and is perhaps now a dead letter in [illegible] law, as it is in fact. Each nation retains a [illegible] control over its vessels and their crews, in [illegible] part of the ocean they may be; all crimes and [illegible] meanours committed on board of a ship are ju[illegible] by law, as soon as the vessel reaches the co[illegible] which it belongs.

ALE FISHERIES.

pecies, in the first instance, much repetition may
tely be spared.
size of the common whale was the subject of
exaggerated notions until within a very recent
l. About fifty years ago, a standard writer in
al history asserted that whales were frequently
e seen above an hundred and sixty feet long;
nt, even at this standard, the animal was much
r than it had been before man began to disturb
estroy the race. That whales "two hundred and
et in length" were often seen previously, is re-
ated as a thing beyond all question. Mr Scoresby,
er, a very high authority on the subject, declares
he common whale seldom or never exceeds seventy
length, and is much more frequently under sixty.
f three hundred and twenty-two whales which he
ersonally aided in capturing, *not one* exceeded
ight feet; and the largest ever taken, of which he
the reported measurement to be authentic, came
ly to sixty-seven feet. The body of a large indi-
of this family measures from thirty to forty feet
the body at the thickest point, or a short way
the head, which is of great proportionate size,
ecupies about one-third of the whole extent from
to tail. When the mouth is open, it is sufficiently
and long to admit a whaler's jolly-boat with its
mplement of men. The bulk of the head, which
newhat conical in form, and has a sort of round
nce above and posteriorly, renders the aspect of
ysticetus clumsy and unshapely. A very slight
ution of the circumference indicates the position
neck, and behind this the body swells to its
est calibre, whence it tapers sharply away again
ds the tail. The animal has no back or dorsal

to the body. This appendage is placed horizontally, and is about twenty-four feet broad. It is an instrument of immense power, and the whale has sometimes given a stroke with it which has sent large boats high into the air in a thousand splinters. The colour of the body is mainly a velvety black; the under part of the head and abdomen, and the junction of the tail, being partly white and partly of a freckled grey. In old whales, much more of the body assumes the latter tint, and the streaks sometimes resemble a beautiful landscape of trees. On the tail, in one instance noticed by Ray, nature, in a freakish mood, had set down the number 122, in large and very distinct characters. The eyes of the whale are about a foot behind the angle of the mouth, and are not much larger than those of the ox. The iris is of a white colour, and the organs are guarded by lids and lashes as in quadrupeds. The two blow-holes of the whale, situated on the summit of the head, and descending perpendicularly through it for a length of twelve inches or so into the top of the windpipe, are the only other features worthy of notice in the exterior aspect of the Greenland whale.

The mouth of the common whale is an organ of very wonderful construction. In a large specimen of the race, it may measure, when fully opened, about sixteen feet long, twelve feet high, and ten feet wide—an apartment, in truth, of very goodly dimensions. It contains no teeth, and enormous as the bulk of the creature is, its throat is so narrow that it would choke upon a morsel fitted for the deglutition of an ox. An inch and a half is stated to be the diameter of the gullet in the very largest whales. From this peculiarity of formation, it may be anticipated that the food of the animal is of a very minute nature, notwithstanding the vastness of the cavity which is prepared for its primary reception. The animal is indeed supported upon a multitude of smaller inhabitants of the deep, and, to permit this, its mouth is provided with a remarkable apparatus, composed of what is called the *baleen*, or the well known *whalebone* of commerce. The baleen is arranged in two rows of laminæ or thin plates, projecting laterally from a line in the centre of the arch of the palate, somewhat like the laminæ of a feather. Towards the point of origin, they are comparatively few in number and strong, while towards the lips they divide and taper away into mere bristles, forming a loose hanging fringe or border. There are about three hundred of these plates on each side, and, when dried, they weigh usually above a ton. In the rorqual whale they are more numerous, and we find from the description, given by Mr Frederick J. Knox, of the skeleton prepared and exhibited at Edinburgh, that three hundred and fourteen external plates were counted on each side in the mouth of that animal. The whole number of plates which *could* be counted, not including the more minute bristly terminations, was 3768. The longest plate of baleen, which is always placed about the centre of the series on each side, measured two feet two inches in length by fifteen inches in breadth. "The substance when recent (says Mr Knox) is highly elastic."

The use of these plates, with their pendulous extremities and fringes, is to retain, as in a net, the multitude of small animals which are floated into the mouth of the whale whenever it is opened. Were it not for such a drainer, formed by these fringes with the aid of the tongue, which is merely a great mass of fat tied down to the lower jaw, the emission of the water would be attended by the escape of all the objects which entered with it. As it is, the most minute matters are retained; and shrimps, sea snails, small crabs, medusæ, &c., are thus entrapped to support the great monster of the deep.

The remaining features in the structure of the whale need not be individually described at the same length. *The skin consists*, first of the scarf-skin, or epidermis, *which is moistened* by an oily fluid, enabling it to resist *the action of water*; secondly, of the *rete* mucosum, a *layer usually held* to contain the colouring matter of *all animal surfaces*; and, thirdly, of the true skin, which, for particular purposes, is open in texture to contain oil, or blubber as it is called, in great tities. This mass of oil, surrounding the whole and sometimes weighing more than thirty ton serves the important end of keeping the anima by its weak conducting powers, amid the coldest of the polar ocean, and is also calculated to re enormous pressure to which the body of the must be subjected at the depths to which descends. Whales have been known to take perpendicularly down to the full extent of a had not this ample layer of fat, between one feet thick, been wrapped around them, posse resisting power like that of caoutchouc, it is dif imagine how, in such a case, they could end immense weight of superincumbent water. Ma being inferior in specific gravity to the water, it is that all this body of oil must be of incalculabl augmenting the buoyancy of the animal's frame. the skin are situated the muscles or flesh, and t racter of this structure is much the same in th as in the ox or horse. With the exception of the arrangement of the various muscles of th does not differ very much from that of quad and the same remark applies to the osseous str The fins are merely rudimental arms, containing the same bones as in man, and the chest struc sembles that of ordinary quadrupeds. The v column of the rorqual whale contains sixty-three those of the Greenland whale are not quite so rous. The skull consists of the crown-bone, fro the facial bones and upper jaw project forward the lower jaw is composed of two long curved that meet at the point or fore-part of the mouth. are often put up over gates, and make a han archway. The whole of these bones are lar porous, and some of them, as the lower jaw-bone tain oil, but they are said to have no proper med marrow. The total weight of Dr Knox's skeleton was twenty-eight tons.

The organs of respiration in the whale are upon the same principle as those of land anim with modifications to suit the peculiar element in the creature lives. It is plain that some provisi required to permit the whale to breathe with risk of having the lungs filled with water. This complished by the extension of the top of the pipe into the nostrils or blowholes, or rather in passage which terminates in these in the common By this contrivance, the creature can inhale air it is feeding or has its mouth full of water. A terrestrial animals, the air gives a red colour blood, or, in other words, oxygenates it, and s the animal heat. The whale has frequently to c the surface, accordingly, to get its air, but this tion is rendered less frequently necessary by the sion of a reservoir of oxygenated blood, which drawn upon when required. This is the cause w animal has such a vast proportionate quantity of in its frame. The brain of the whale is held by to be large in relation to the animal, but no de nate conclusions have been reached on the s The arrangements of the whole nervous syste equally little understood. It is known that whales pretty acute vision, but there is a doubt whether they have any external ear. Their sense of smell to lie in the blow-holes, yet the strongest reas ascribing such a faculty to them at all is founded the half-traditionary notion of sailors, that if strong smelling substances are thrown over whales will fly from the spot at once. The mamm dugs of the common whale are two in numbe attached to the abdomen; in the case of some varieties, they are placed on the breast. In both they are situated inferiorly. The milk of the is said to be rich and creamy.

Such are the general characters of structure whale tribe, and, on regarding them attentively cannot but feel amazed at the seeming simplici

sure of success. And here nature is again by a singular coincidence, discoverable in the map of the world, most coasts and con- in a northern and southern direction. Hence ttached, by seamen, to an accurate know- e latitude; and hence the saying of "Lati- and look-out." Although, as we have stated, s follow a northern and southern direction, et not a few which lie east and west, so that g them are only determined by the longitude. to have the satisfaction, not merely to run long the chart, and say, "I am somewhere parallel," but to be able to point to the spot, I am there," is, to the nice navigator, no motive.

TO FIND THE LONGITUDE.

ways have been devised to find the longitude, ich the great element is time. The earth per- diurnal revolution in 24 hours, or, in other h part of the circumference of the globe, livided into 360 degrees, is brought under ce a-day. Hence, each part of the circum- ckoning from east to west), has its own pecu- f day. When it is noon at one place, it is afternoon at another place, two at another, the time differs all round the globe. Divid-) degrees by 24, we find that 15 is the result; 5 degrees, therefore, along the circumference, twards, there is an hour of difference, in nd, going eastwards, an hour behind. If it Greenwich, it will be one o'clock at a point s east from it (that is, the sun has passed hour ago), and eleven o'clock forenoon at a egrees west from it (that is, the sun will be getting up to it). Dividing the 60 minutes by 15, the result is 4; the earth, therefore, ler the sun at the rate of a degree, or 60 al miles, in four minutes, or 15 miles in the one mile in the four seconds, or a quarter of he second. Here, then, the element of time at once, and in the most satisfactory manner, on the distance of any given place, east or any other given place. The measuring of ance is called finding the longitude. Different the globe have been established as starting making these measurements. The French m Paris, and the English from Greenwich, ear London, where an astronomical obser- s been long established and supported at the pense. In all English works of geography, ude is reckoned from Greenwich, although sly mentioned. Navigators determine their by watches or chronometers, whose movements act as can possibly be obtained from mecha- setting out on a voyage, the chronometer is don time, and kept going at that time. At of noon of each day, as determined by an n with the sextant, the difference is estimated hat hour and the hour indicated by the chro- and that difference is the longitude east or reenwich, as the case may be. Some mari- security, take several chronometers to sea , as one only is by no means a safe guide. In however, the masters of coasting traders, or pursue short voyages by regular lines of pend on books containing lists of longitudes of latitudes.

MARINE BAROMETERS.—LOG-BOOK.

t great requisite in navigation is a good baro- indicate the approach of foul weather. The ate instrument of this kind is the sympeso- Adie, by which the earliest and most certain s are presented of coming storms. In treating ture and value of instruments of this nature, t makes the following observations:—"The captain of the present day, trusting to this nary monitor, is frequently enabled to take in sail and to make ready for the storm, when in former times the dreadful visitation would have fallen upon him unprepared. The marine barometer has not been in general use for many years, and the author was one of a numerous crew who probably owed their preser- vation to its almost miraculous warning. It was in a southern latitude. The sun had just set with placid appearance, closing a beautiful afternoon, and the usual mirth of the evening watch was proceeding, when the captain's order came to prepare with all haste for a storm. The barometer had begun to fall with appalling rapidity. As yet, the oldest sailors had not perceived even a threatening in the sky, and were surprised at the extent and hurry of the preparations: but the required measures were not completed, when a more awful hurricane burst upon them than the most expe- rienced had ever braved. Nothing could withstand it; the sails, already furled and closely bound to the yards, were riven away in tatters: even the bare yards and masts were in great part disabled; and at one time the whole rigging had nearly fallen by the board. Such, for a few hours, was the mingled roar of the hurricane above, of the waves around, and of the incessant peals of thunder, that no human voice could be heard, and amidst the general consternation even the trumpet sounded in vain. In that awful night, but for the little tube of mercury which had given the warning, neither the strength of the noble ship, nor the skill and energies of the commander, could have saved one man to tell the tale. On the following morning the wind was again at rest, but the ship lay upon the yet heaving waves, an unsightly wreck."

A journal of events and observations on board ship is usually kept in what is called the log-board, and transferred thence into the log-book. The log-board consists of two boards shutting together like a book, and divided into several columns, containing the hours of the day and night, the direction of the winds, and the course of the ship, with all the material occurrences that happen during the twenty-four hours, or from noon to noon, together with the latitude of observation. From this table, which is written in chalk and daily effaced, the officers work the ship's way, and compile their journals. From it, also, entries are carried to the log-book, in an expanded form, with any observations and additional particulars supposed to be necessary. The log-book is thus the journal of the ship, and is preserved with great care for exhibition, if required, at the termination of the voyage.

Thus, then, by the use of various instruments and practical experience in navigation, a ship is conducted from port to port, dangers avoided and difficulties over- come. Though they who traverse the vast ocean leave no track for the guidance of those who follow, it is thus converted into a plain and convenient highway, extend- ing to the extremities of the earth.

SAILING.

It is important that young men, in acquiring in- struction in navigation, should also make themselves acquainted with the laws of fluid and atmospheric action. These are treated of in other parts of the present work, and need here be only alluded to in a general way in reference to the sailing of vessels.

A ship at sea depends principally on the winds as a means of impulsion to its destined port. In moving through the water, it encounters a certain resistance which must be overcome by the pressure on the sails. The degree of this resistance depends on the shape of the vessel, and also on the degree of speed to which the vessel is urged in its course. Of the proper shape of the vessel to give the least possible resistance, we have the best of all examples in those which nature has pre- sented to our observation in the form of the duck and other water-fowl, and also in the trout, haddock, salmon, and various other kinds of fish. In all these natural models, the form is that of a wedge with the broad end foremost, leaving the narrow tapering end behind to allow the displaced fluid to disperse itself freely. Thus,

it is of less importance to have sharp bows to cleave the water, than to have a *fine run* or gradual taper from bows to stern. Of this peculiarity of construction we shall hereafter speak in the article SHIPS; our object at present is chiefly to notice the principle of resistance in relation to the speed. According to the laws of liquids, *the resistance presented by the water increases as the square of the speed*, that is, the resistance is four times greater with only a double rate of speed. This law of fluid action is simply and beautifully explained by Dr Arnot. "A boat which moves one mile per hour, displaces a certain quantity of water, and with a certain velocity; if it move twice as fast, it of course displaces twice as many particles in the same time, and requires to be moved by twice the force on that account; but it also displaces every particle with a double velocity, and requires another doubling of the power on this account: the power thus being doubled on two accounts, becomes a power of four. In the same manner, with a speed of three, three times as many particles are moved, and each particle with three times the velocity; therefore, to overcome the resistance, a force of nine is wanted; for a speed of four, a power of sixteen; for a speed of five, a power of twenty-five, and so forth. Thus, even if the resistance at the bow [fore part] of a vessel were all that had to be considered, the force of 100 horses would only drag the vessel ten times as fast as the force of one horse. But there is another important element in the calculation, namely, the lessening, as the speed quickens, of the usual water pressure on the stern [hind part], which pressure, while she is at rest, is equal to the pressure on the bow; and the force, therefore, required to produce an increased velocity is still considerably greater than that noted. There is not a more important truth in physics than the law of fluid resistance to moving bodies, here treated of; it explains so many phenomena of nature, and becomes a guide in so many matters of art.

We shall now (continues the Doctor) set forth some interesting examples. It explains at what a heavy expense of coal high velocities are obtained in steam-boats. If an engine of about 50 horse power would drive a boat 7 miles an hour, two engines of 50, or one of 100, would be required to drive it 10 miles, and three such to drive it 12 miles; even supposing the increased resistance at the bow, as already stated, to be the measure of the whole work done, which it is not, and that engines work to the same advantage with a high velocity as with a low, which they do not. For the same reason, if all the coal which a ship could conveniently carry were just sufficient to drive her 1000 miles, at the rate of 12 miles per hour, it would drive her much more than 3000 at a rate of 7 miles per hour; and much more than 6000 at a rate of 5 miles per hour. This is a very important consideration for persons concerned in steam navigation to distant parts.

The same law shows the folly of putting very large sails on a ship; there being a disadvantage in point of speed by no means compensating for the additional expense of making and working the sails, and the risk of accidents in bad weather. The ships of the prudent Chinese have not, for the same tonnage, one-third so much sail as those of Europeans, and yet they move but a little slower on that account. A European ship under jury masts does not lose so much of her usual speed as most people would expect.

The law explains also why a ship glides through the water better when there is very little wind, although with a strong breeze she would only sail at the rate of four or five miles. Less than the 100th part of that force of wind which drives her 10 miles an hour, would drive her 1 mile per hour, and less than the 400th part would drive her half a mile. Thus, also, during a calm, a few men pulling in a boat can move a large ship at a considerable rate.

These considerations show strikingly of what importance to navigation it might be to have, as a part of a ship's ordinary equipment, one or two water-wheels, to be affixed upon the ship's side when required, like the paddle-wheels of a steam-boat, and by turning which the crew might deliver themselves from the tedium, or even disastrous consequences, of a long calm at sea."

The impulse which a vessel at sea receives from the wind, is generally of greater value when given in some degree sideways, than when direct on the stern, at least it is so when there are several masts and sails. The reason of this is very obvious: when the wind blows directly astern, it can only affect one or perhaps two sails with any commensurate force; but when it blows slantingly on the vessel in the direction of its course, every sail in the ship may be trimmed to meet the breeze, and so all receiving an equally powerful impulse, a corresponding effect is produced. It is one of the prime arts in seamanship so to trim or arrange the sails of a vessel, as to take advantage of a wind which is almost right ahead. This is called sailing close to the wind. Some vessels, by tacking, or sailing in a zig-zag direction, can be made to proceed within a very few points of the wind, and thus are always getting on a little in their course, while others, less favourably rigged and managed, would be compelled to lay to or stop. Dr Arnot suggests a method by which vessels might be made to steer, that is, guide, themselves through the ocean, particularly in cases of emergency.

"It is possible to make a ship or boat steer itself, by placing a powerful vane on the mast-head, and connecting it with the tiller-ropes by two projecting arms from its axis. If it were desired to make the ship sail directly before the wind, the tiller-ropes would be fixed to the vane, so that the helm should be in the middle position when the vane were pointing directly forward: should the vessel, then, from any cause deviate from her course, the vane, by its changed position with respect to her, would have produced a corresponding change on the position of the helm, and just such as to bring her back to her course. Again, it is evident that, by adjusting such a vane and rudder to each other in different ways, any other desired course might be obtained, and which would alter only with the wind. The vane would require to be of large size to have the necessary power; a wide hoop, for instance, with canvass stretched upon it; and the rudder, that it might turn with little force, would be hung on an axis passed through its middle, instead of, as usual, by hinges at one edge. Cases have occurred where shipwrecked persons might have sent intelligence of their disaster to a distant coast by a small vessel, or even a block of wood fitted up in this way; and the method might sometimes save an additional hand in a boat's crew."

DOMINION OF THE SEAS.

It is a common law of nations that the ocean is a free and universal highway, which no state can appropriate to its own especial use. While this exists as a principle generally recognised by all civilised powers, Great Britain has for a considerable period of time claimed *the dominion of the seas*, as a right acquired by extensive conquest, and the skill and valour of its seamen. By this claim, it is not assumed that Great Britain possesses a legal right of property in the waters of the ocean, or the lands which they may cover. The claim resolves itself into what is termed in law "a military sovereignty," which it would be exceedingly difficult to define, and is practically an empty and inglorious boast. Within the last twenty years, during which a large maritime force has grown up in France, Russia, and the United States of America, yielding to the British to the dominion of the seas [illegible] heard of, and is perhaps now a dead letter in point of law, as it is in fact. Each nation has a perfect control over its vessels and their crews, or wherever part of the ocean they may be; all crimes and misdemeanours committed on board a ship are punishable by law, as soon as the vessel reaches the country to which it belongs.

Printed and Published by W. and R. CHAMBERS, Edinburgh.

e whale is, will furnish it with no contemptible mouth-
l. In the gullet of one spermaceti whale, an arm or
ntaculum of a sea-squid was found, measuring nearly
enty-seven feet long. The native divers of the South
as have a mortal dread of these squids, and no wonder,
eing that the strength of man is totally inefficient to
ar away their tentacula when they are once fixed. A
val captain, we are informed by Sir Grenville Temple,
ce came in contact with a large sepia when bathing.
e animal attached itself to one foot; he felt this, and
rove to disengage the creature with the other foot,
t it fixed upon that too. He seemed then to have
ade an attempt to free himself with his hands. These
so were firmly grasped, and the poor man was soon
ter found bound hand and foot, and drowned past re-
very! Mr Beale relates an adventure which he him-
lf had with one of these creatures. He saw it near
e surf on one of the Bonin islands, and made some
lf sportive attempts to capture it, not anticipating
y possible harm from a creature which had a blubbery
dy not above the size of a clenched fist, though its
ntacles appeared about two feet in length. He took
ld of one of them, and was endeavouring to pull
e creature from the rock, when suddenly it turned
und and sprang upon his arm, which had been bared
r the purpose of seeking shells. It fastened its cold
my body upon him so firmly that he was in great
arm, especially as it endeavoured to fix its mouth
ext. He ran to the boat to his friends, and the animal
as disengaged, but only by cutting it in pieces. These
uids are very numerous in the Pacific seas, and the
erm-whale has abundant feeding upon them and other
all fishes.

The cachalot is seldom or never seen in the Green-
nd seas, at least by modern navigators. It is spread,
owever, over an immense expanse of the ocean, having
en captured, at some time or other, almost every
here between the latitude of 60° south and 60° north.
he coasts of New Guinea and the adjacent archipe-
goes, the shores of New Holland, Mitchell's Group,
ew Zealand, Navigator isles, Ellis's Group, the shores
Peru, Chili, California, Japan, the Persian Gulf, the
hinese seas, the Molluccas, and many other parts of
e ocean, abound more or less with this valuableceta-
ous tribe.

In the Naturalist's Library, an able periodical, under
e conduct of Sir William Jardine, we find the follow-
g minor genera of whales enumerated, after a descrip-
on of the mysticetus, the rorquals, and the cachalot,
e three varieties of greatest use to man. 1st, The
arwhal, or sea-unicorn, an animal from sixteen to
venty feet long, and provided with a straight tusk or
orn (sometimes two), about four or five feet in length,
id projecting from the snout. The animal has a
otted, greyish body, handsomely rounded off, and
ntaining usually near a ton of oil, much prized by
e Greenlanders, on whose coasts the narwhal is often
en. The horn yields beautiful ivory, and is greatly
ught on that account. 2d, The diodons, or two-toothed
hales. These are of a size similar to the preceding,
nd are a variety of little or no value. 3d, The hype-
odons, animals of a dark colour, about twenty feet
ng, and distinguished by knobs in place of teeth.
th and 5th, The aodons and the xiphius, two classes
f small toothless whales. 6th, The beluga, or white
hale, a creature of pure white colour, exceedingly
ounded and symmetrical in form, and from twelve to
wenty feet long. It abounds on the northern coasts
f Asia and America. In 1815, a beautiful specimen
f the race haunted the Forth for three months, and
as finally killed, and placed in the Edinburgh Museum.
th, The delphinapterus, a South-sea whale, is about six
et long, and remarkable only for being beaked some-
hat like a bird. 8th, The deductor is an Arctic animal,
lack in colour, and twenty or twenty-four feet long.
t has scarcely any snout, and is most noted for its
ower of uttering loud cries when in distress, which
ircumstance has obtained for it the name of the *ca'ing*
calling) whale. Whether other species can cry or sea-

to the body. This appendage is placed horizontally, and is about twenty-four feet broad. It is an instrument of immense power, and the whale has sometimes given a stroke with it which has sent large boats high into the air in a thousand splinters. The colour of the body is mainly a velvety black; the under part of the head and abdomen, and the junction of the tail, being partly white and partly of a freckled grey. In old whales, much more of the body assumes the latter tint, and the streaks sometimes resemble a beautiful landscape of trees. On the tail, in one instance noticed by Ray, nature, in a freakish mood, had set down the number 122, in large and very distinct characters. The eyes of the whale are about a foot behind the angle of the mouth, and are not much larger than those of the ox. The iris is of a white colour, and the organs are guarded by lids and lashes as in quadrupeds. The two blow-holes of the whale, situated on the summit of the head, and descending perpendicularly through it for a length of twelve inches or so into the top of the windpipe, are the only other features worthy of notice in the exterior aspect of the Greenland whale.

The mouth of the common whale is an organ of very wonderful construction. In a large specimen of the race, it may measure, when fully opened, about sixteen feet long, twelve feet high, and ten feet wide—an apartment, in truth, of very goodly dimensions. It contains no teeth, and enormous as the bulk of the creature is, its throat is so narrow that it would choke upon a morsel fitted for the deglutition of an ox. An inch and a half is stated to be the diameter of the gullet in the very largest whales. From this peculiarity of formation, it may be anticipated that the food of the animal is of a very minute nature, notwithstanding the vastness of the cavity which is prepared for its primary reception. The animal is indeed supported upon a multitude of smaller inhabitants of the deep, and, to permit this, its mouth is provided with a remarkable apparatus, composed of what is called the *baleen*, or the well known *whalebone* of commerce. The baleen is arranged in two rows of laminæ or thin plates, projecting laterally from a line in the centre of the arch of the palate, somewhat like the leaves of a book. Towards their point of origin, they are comparatively few in number and strong, while towards the lips they divide and taper away into mere bristles, forming a loose hanging fringed border. There are about three hundred of these plates on each side, and, when dried, they weigh nearly a ton. In the rorqual whale they are more numerous, and we find from the observations, given by Dr Jonathan Knox, of the one exhibited at Edinburgh, that three hundred and forty-two plates were counted on each side of the mouth of that animal. The whole number of plates which could be counted, not including the more minute fringy portions, was 3708. The longest plates of baleen, which is always placed about the centre of the series, could be measured two feet two inches in length by the above-named gentleman. "The substance which we call whalebone," says Dr Knox, "is very elastic."

The use of these plates, we think, is now completely established. The whale, in taking its food, opens its mouth, and the water rushes in with the animalcules which are destined for its nourishment. Were it not for such a contrivance, these animalcules, with the addition of a large mass of the fluid they are in, would occupy a great space of the stomach, and thus prevent the animal from receiving by the mouth a sufficient quantity of its proper food. As soon as the water has entered the mouth, the tongue, which is very large, is pressed against the roof of the mouth, and the water is forced out through the baleen, which retains the animalcules, and prevents them from escaping with the great mass of water.

There is another feature in the structure of the whale worthy of notice. Under the skin there is a layer of fat, which, in the case of the rorqual whale, is about two feet in thickness, and is evidently intended to resist the cold of the water. This fat, or *blubber*, as it is commonly called, a layer of which is found in all the true whales, which, for particular purposes, is open in texture, so as to contain oil, or blubber as it is called, in great quantities. This mass of oil, surrounding the whole animal, and sometimes weighing more than thirty tons in all, serves the important end of keeping the animal warm by its weak conducting powers, amid the coldest recesses of the polar ocean, and is also calculated to resist the enormous pressure to which the body of the creature must be subjected at the depths to which it often descends. Whales have been known to take a line perpendicularly down to the full extent of a mile, and had not this ample layer of fat, between one and two feet thick, been wrapped around them, possessing a resisting power like that of caoutchouc, it is difficult to imagine how, in such a case, they could endure the immense weight of superincumbent water. Moreover, being inferior in specific gravity to the water, it is obvious that all this body of oil must be of incalculable use in augmenting the buoyancy of the animal's frame. Below the skin are situated the muscles or flesh, and the character of this structure is much the same in the whale as in the ox or horse. With the exception of the tail, the arrangement of the various muscles of the whale does not differ very much from that of quadrupeds, and the same remark applies to the osseous structure. The fins are merely rudimental arms, containing nearly the same bones as in man, and the chest strongly resembles that of ordinary quadrupeds. The vertebral column of the rorqual whale contains sixty-three bones, those of the Greenland whale are not quite so numerous. The skull consists of the crown-bone, from which the facial bones and upper jaw project forward, while the lower jaw is composed of two long curved bones, that meet at the point or fore-part of the mouth. These are often put up over gates, and make a handsome archway. The whole of these bones are hard and porous, and some of them, as the lower jaw-bones, contain oil, but they are said to have no proper medulla or marrow. The total weight of Dr Knox's rorqual skeleton was twenty-eight tons.

The organs of respiration in the whale are formed upon the same principle as those of land animals, with modifications to suit the peculiar element in which the creature lives. It is plain that some provision is required to permit the whale to breathe without the risk of having the lungs filled with water. This is accomplished by the extension of the top of the windpipe into the nostrils or blow-holes, or rather into a passage which terminates in two in the common whale. By this contrivance, the creature can inhale air when it is feeding or has its mouth full of water. As in terrestrial animals, the air gives a red colour to the blood, or, in other words, oxygenates it, and warms the animal heat. The whale has frequently to rise to the surface, accordingly, to get its air, but this operation is rendered less frequently necessary by the possession of a reservoir of oxygenated blood, which can be drawn upon when required. This is the cause why the animal has such a vast proportionate quantity of blood in its frame. The brain of the whale is known to be large in relation to the animal, but no other conclusions have been reached on the subject. The arrangements of the whale nervous system are equally little understood. It is known that the animal has pretty acute vision, but there is a doubt whether or not they have any external ear. There seems no doubt as to the blow-holes, yet the best-informed whalers do not seem a faculty to the animal in question. The ordinary notion of sailors, that whales, when struck, sometimes spout blood instead of water, which is only from those spouting. The nipples of the common whale are two in number, and attached to the abdomen; in the case of some other species, they are placed on the breast. In both cases they are situated very poorly. The limbs of the animal are said to be rich and creamy.

Such are the general characters of structure in the whale tribe, and, on regarding them attentively, one cannot but feel amazed at the seeming simplicity with

ep them from being overboated by friction, and a few
ier articles, are also laid down in the boats for use.

MODE OF FISHING.

Whenever there is a probability of seeing whales,
master, or some experienced officer, keeps a close
k-out from the crow's-nest, a station at the mast-head
called. With the assistance of a telescope, he scans
surface of the waters around, ready, at the first
mpse of a fish, to give notice to the watch on deck.
fine weather, a boat is kept afloat, manned, and
gaged also in the look-out. The short time during
hich whales usually remain above water to breathe
eing only two minutes), renders the discovery of them
s easy than might be anticipated from their great
lk. Besides, while below water, the animal frequently
verses a space of half a mile in the ten or fifteen
inutes intervening between the respirations; and hence
e spot at which it may again rise, after being once
en and again disappearing, is left in a great measure
subject of conjecture. The previous direction of the
hale's movements, and occasionally a sort of eddy on
e surface, are the only guides to the boatmen in this
rticular. When the whale does come up within reach
a harpoon-cast, and lies unconscious of the approach
its enemies, "then (says Captain Scoresby) the
rdy fisher rows directly upon it, and an instant
fore the boat touches it, buries his harpoon in its
ck. But if, while the boat is yet at a little distance,
e whale should indicate his intention of diving, by
ting his head above the common level, and then plunge
g it under water, and raising its body until it appear
e the large segment of a sphere, the harpoon is
rown from the hand, or fired from a gun, the former
which, when skilfully practised, is efficient at the
stance of eight or ten yards, and the latter at the dis-
nce of thirty yards or upwards. The wounded whale,
the surprise and agony of the moment, makes a con-
lsive effort to escape. Then is the moment of danger.
he boat is subjected to the most violent blows from
head or its fins, but particularly from its ponderous
l, which sometimes sweeps the air with such tremen-
us fury, that both boat and men are exposed to one
mmon destruction.

The head of the whale is avoided, because it cannot
penetrated with the harpoon; but any part of the
dy between the head and tail will admit of the full
ngth of the instrument, without danger of obstruction.
he harpoon, therefore, is always struck into the back,
d generally well forward towards the fins, thus afford-
g the chance, when it happens to drag and plough
ong the back, of retaining its hold during a longer
me than when struck in closer to the tail.

The moment that the wounded whale disappears, or
aves the boat, a jack or flag, elevated on a staff, is
splayed, on sight of which, those on watch in the ship
ve the alarm, by stamping on the deck, accompanied
y a simultaneous and continued shout of 'a fall!'* The
eeping crew, roused by the sound, jump from their
ds, rush upon deck, with their clothes tied by a
ring in their hands, and crowd into the boats, at a
mperature of zero. They generally contrive to dress
emselves, in part at least, as the boats are lowered
own; but sometimes they push off in the state in which
ey rise from their beds, row away towards the 'fast
oat,' that is, the boat attached by its harpoon and line,
the whale, and have no opportunity to clothe them-
lves for a length of time afterwards. The alarm of
a fall' has a singular effect on the feelings of a sleeping
rson, unaccustomed to the whale-fishing business.
has often been mistaken for a cry of distress. A
ndsman in a Hull ship, seeing the crew, on the occa-
on of a fall, rush upon deck, with their clothes in their
nds, when there was no appearance of danger, thought

* The word 'fall,' as well as many others used in the fishery,
derived from the Dutch language. In the original it is written
l, implying jump, drop, fall, and is considered expressive of
e conduct of the sailors when manning the boats, on an occa-
on requiring extreme dispatch.

imaginary shelter; or it returns instantly to the surface, and gives evidence of its agony by the most convulsive throes, in which its fins and tail are alternately displayed in the air, and dashed into the water with tremendous violence. The former behaviour, however, that is, to dive towards the bottom of the sea, is so frequent, in comparison of any other, that it may be considered as the general conduct of a fast fish.

A whale struck near the edge of any large sheet of ice, and passing underneath it, will sometimes run the whole of the lines out of the boat, in the space of eight or ten minutes of time. This being the case, when the 'fast boat' is at a distance, both from the ship and from any other boat, it frequently happens that the lines are all withdrawn before assistance arrives, and, with the fish, entirely lost. In some cases, however, they are recovered. To retard, therefore, as much as possible, the flight of the whale, it is usual for the harpooner who strikes it, to cast one, two, or more turns of line round a kind of post, called a ballard, which is fixed within ten or twelve inches of the stern of the boat for the purpose. Such is the friction of the line, when running round the ballard, that it frequently envelopes the harpooner in smoke; and if the wood were not repeatedly wetted, would probably set fire to the boat. During the capture of one whale, a groove is sometimes cut in the ballard, near an inch in depth; and were it not for a plate of brass, iron, or a block of lignum vitæ, which covers the top of the stem where the line passes over, it is apprehended that the action of the line on the material of the boat would cut it down to the water's edge, in the course of one season of successful fishing. The approaching distress of a boat, for want of line, is indicated by the elevation of an oar, in the way of a mast, to which is added a second, a third, or even a fourth, in proportion to the nature of the exigency. The utmost care and attention are requisite, on the part of every person in the boat, when the lines are running out; fatal consequences having been sometimes produced by the most trifling neglect. When the line happens 'to run foul,' and cannot be cleared on the instant, it sometimes draws the boat under water; on which, if no auxiliary boat or convenient piece of ice be at hand, the crew are plunged into the sea, and are obliged to trust to the buoyancy of their oars, or to their skill in swimming, for supporting themselves on the

whale-fishing is apt to be impeded, as may be imagined, by the great masses of ice every abounding in the northern seas. The usual of proceedings in open water has been described; rent circumstances, different plans must be l. *Pack-fishing* is the name given to the chase whale on the borders of close packs of drift-ice. imal loves to shelter his vast bulk under the lee frozen masses, and, when struck, usually flies for refuge, thus endangering the lines and lives whalemen. The common method of providing such contingencies, is either to strike the fish wo harpoons from different boats at the same t, or to affix the line of a second boat to that of from which the whale has been harpooned, so e strength of two lines is brought into play the fish. Sometimes, when a fish gets entangled drift-ice, the adventurous seamen climb over it, ice the animal from that perilous station. Also- pack-fishing is troublesome and dangerous, and not that the largest whales often resort to such ns, whalers would seldom attempt to fish there. the other hand, *field-fishing*, as it is called, or on the edges of those wide connected plains of med fields, is one of the most productive of all des of fishing prosecuted in the Greenland seas. the weather is tolerably mild, it is also a pretty mode. The most marked of the advantages held field-fishing, is the curtailment of the range of ale's movements. When harpooned, it com- descends obliquely beneath the field, and, being to rise through the ice, is forced to return to ge, or nearly to the spot where it made the . Thus, the ship's boats, if stationed along the of the field, can at once harpoon it a second and dispatch it. In open water, the whale, by at a spot far apart from where it dived, gains breathe freely and recruit its strength, and so breaks away altogether, or greatly protracts the e. For this reason, six boats at a field will do rk of twelve in open sea. Two or more fish are ntly taken at a field at one time, and on a parti- occasion six fish were actually captured at once seven boats of a single ship. Even in such r as renders fishing impracticable elsewhere, shing can be prosecuted with success. But there advantages also attendant on this mode. The ents of fields of ice are so rapid, various, and untable, and their powers of doing mischief so ted, that the utmost prudence and skill cannot en- secure vessels lying in their vicinity from the risk re damage or total destruction. Small fields or re especially dangerous, particularly if they con- mall cracks or holes in the centre of them. The of a sudden movement in such floes is much r than in the case of the large fields, and, more- after being struck, the whale generally makes for ertures in the ice, and there breathes freely, ing it necessary for the men to cross the field on nd dispatch their prey with the lance. Even they succeed in doing this, there is no way of out the whale but by sinking it, and dragging below the ice, at the great risk of pulling out rpoon altogether; or by cutting the blubber and transporting it over the surface of the floe, by piece. These operations are attended with bour and loss of time. "As connected with this t (says Captain Scoresby), I cannot pass over a stance which occurred within my own observa- and which excited my highest admiration. On h of July 1813, the ship Esk lay by the edge of t of ice, in which were several thin parts, and holes. Here a fish being heard blowing, a har- with a line connected to it, was conveyed across e from a boat on guard, and the harpooner suc-

officers lamented this circumstance, and expressed a wish that the harpoon were better fast; observing, at the same time, that if it should slip out, the whale would either be lost or they would be under the necessity of cutting it up where it lay, and of dragging the pieces of blubber over the ice to the ship—a kind and degree of labour which every one was anxious to avoid. No sooner was the wish expressed, and its importance made known, than one of the sailors, a smart and enterprising fellow, stepped forward and volunteered his services to strike it better in. Not at all intimidated by the surprise which was manifested in every countenance by such a bold proposal, he pulled out his pocket-knife, leaped upon the back of the living whale, and immediately cut the harpoon out. Stimulated by this courageous example, one of his companions proceeded to his assistance. While one of them hauled upon the line and held it in his hands, the other set his shoulder against the extremity of the harpoon, and though it was without a stock, he contrived to strike it again into the fish more effectually than it was at first; the fish was in motion before they finished. After they got off its back, it advanced a considerable distance, breaking the ice all the way, and survived this uncommon treatment ten or fifteen minutes. This admirable act was an essential benefit. The fish fortunately sank spontaneously after being killed, on which it was hauled out to the edge of the ice by the line, and secured without further trouble. It proved a stout whale, and an acceptable prize."

If whalers could choose their own ground for fishing, many of them would probably prefer a position among open, navigable drift-ice, where the force of the sea is broken, and heavy swells prevented from affecting the vessel. This kind of fishing is called *open pack-fishing*, and is held to be advantageous for the capture of whales. Where the ice is crowded, however, and affords room only for boats to pass through it, the chase becomes difficult and hazardous. Still, as the fishers must take the seas as they find them, fishing is often conducted in this situation of things. Success depends on the boats being spread widely, on the incessant watchfulness of the harpooners, and on their

ceeded in striking the whale at the distance of 350 yards from the verge. It dragged out ten lines (2400 yards), and was supposed to be seen blowing in different holes in the ice. After some time it happened to make its appearance on the exterior, when a harpoon was struck at the moment it was proceeding again beneath. About 100 yards from the edge, it broke the ice where it was a foot in thickness with its crown, and respired through the opening. It then determinately pushed forward, breaking the ice as it advanced, in spite of the lances constantly directed against it. It reached, at length, a kind of basin in the field, where it floated on the surface of the water without any encumbrance from ice. Its back being fairly exposed, the harpoon, struck from the boat on the outside, was observed to be so slightly entangled that it was ready to drop out. Some of the officers lamented this circumstance, and expressed a wish that the harpoon were better fast; observing, at the same time, that if it should slip out, the whale would either be lost or they would be under the necessity of cutting it up where it lay, and of dragging the pieces of blubber over the ice to the ship—a kind and degree of labour which every one was anxious to avoid. No sooner was the wish expressed, and its importance made known, than one of the sailors, a smart and enterprising fellow, stepped forward and volunteered his services to strike it better in. Not at all intimidated by the surprise which was manifested in every countenance by such a bold proposal, he pulled out his pocket-knife, leaped upon the back of the living whale, and immediately cut the harpoon out. Stimulated by this courageous example, one of his companions proceeded to his assistance. While one of them hauled upon the line and held it in his hands, the other set his shoulder against the extremity of the harpoon, and though it was without a stock, he contrived to strike it again into the fish more effectually than it was at first; the fish was in motion before they finished. After they got off its back, it advanced a considerable distance, breaking the ice all the way, and survived this uncommon treatment ten or fifteen minutes. This admirable act was an essential benefit. The fish fortunately sank spontaneously after being killed, on which it was hauled out to the edge of the ice by the line, and secured without further trouble. It proved a stout whale, and an acceptable prize."

If whalers could choose their own ground for fishing, many of them would probably prefer a position among open, navigable drift-ice, where the force of the sea is broken, and heavy swells prevented from affecting the vessel. This kind of fishing is called *open pack-fishing*, and is held to be advantageous for the capture of whales. Where the ice is crowded, however, and affords room only for boats to pass through it, the chase becomes difficult and hazardous. Still, as the fishers must take the seas as they find them, fishing is often conducted in this situation of things. Success depends on the boats being spread widely, on the incessant watchfulness of the harpooners, and on their occasionally taking the benefit of a mass of ice, from the elevation of which the fish may sometimes be seen blowing in the interspaces. Celerity in rowing, and the highest degree of activity in all the proceedings, can alone give a chance of success in open pack-fishing.

Whalers must also be prepared to meet and combat all the difficulties attending the prosecution of their employment in *storms* and *fogs*. When a gale occurs during a chase, and after a fish has been harpooned, fishers are often obliged to cut the lines and let their prize go. Sometimes this takes place even when the fish is killed, and it is worthy of remark that a whale so abandoned becomes the lawful prize of the ship that first gets hold of it, though this may occur in the face of the original captors. But it is common enough for whalers during a storm to keep a fish secured by a hawser to the ship, and to retain it thus till the return of moderate weather. Few whalers venture to commence fishing while a storm exists, and it is a matter of equal difficulty and uncertainty to fish during a fog. The mist on such occasions is so thick that it possible to see objects, however large, above 100 yards off; and when a boat is led away by the e such a distance that a bell or a horn cannot be its situation becomes very perilous. The only these cases is to make every possible exertion rapid dispatch of the whale, and if this be im cable, to leave it.

Captain Scoresby gives an interesting account plan pursued by himself in *bay-ice fishing*. locked up with his ship in a field of thin bay-i was unfit in many places to bear a man's wei placed a number of boats in various openings existed a short way from the vessel. When a came to these apertures to breathe, it was and the men endeavoured to drown it, when it below the ice, by keeping a steady strain on t If this plan failed, Captain Scoresby planted his a pair of ice-shoes, formed simply of thin deal- to the centre of which the feet were tied, and t boldly crossed the thin ice to the point where, direction of the line, he knew the fish would ri three instances he was fortunate enough to whale through the ice and to plunge his harpo its body, after which he used his lance, till in ea the fish was killed. The fish actually rose twice beneath the very spot where he stood, and through the ice with its head. He was lucky to escape all injury, however, though the ice places could not have borne the weight of a boy ing in common shoes. This kind of bay-ice though successful, will be regarded by most per somewhat daring and hazardous.

Of course, in all these various ways of fishin cumstances now and then occur which set at d all ordinary rules. The whale, for example, struck near the margin of a small floe, is usual in restraint, and killed by the use of the lines f most *two* boats. On the 25th of June 1812, ho a harpooner belonging to the Resolution of W struck a fish close by a small floe, under which appeared. Assistance was quickly given, and a boat's lines were attached to those of the fast-b boat attached to the whale), after which it was the other boatmen, who spread out for a second But in a short time distress signals were made fast-boat, and before aid could be afforded, th were seen to throw themselves into the sea. diately afterwards the bow of the boat sank water, the stern rose in the air, and the whole m cally disappeared. An accidental circumstanc prevented the cutting of the lines. The men picked up, and a search commenced for the wha was ere long seen, and no less than three har each having a boat and its lines attached to it buried in the animal's body. Every one imagin all was now secure beyond risk. Not so, however whale pushed impetuously forward, and soon th of one boat found their lines run out, and were to cut them. The harpoon of another boat was out from the body of the fish, and now one boa remained in connection with the animal. The en still darted forward with the velocity of light, a only pulled out the lines of the remaining boat, bu it fly along like an arrow. At length the line and the whale went off free, with a boat and yards, or about 3¾ English miles, of line behind i obstruction to its progress, caused by the sunken and by the lines also, which weighed 35 cwt., have been immense, yet the whale pushed on unabated vigour. It was pursued, and about *ten* from the spot where it was first struck, it was struck by four harpoons, and yielded at length fate. Calculating the additional lines used at the this fish ran out nearly six miles of lines. Th and 31,200 yards of line were lost. After all, the proved to be one but of the second or third size. the largest are by no means the most difficult, in g to kill.

hip to.' But although we managed matters
and secretly as possible, we found, the mo-
boats cleared the ship's side, that all the
been as vigilant as ourselves, and had also
eir boats after the whale. The whole of
ediately began the chase—nine boats in all,
e from each ship. They all exerted them-
eir utmost, and, as we expected, in vain; for
of the boats had got even near him, the
animal lifted his widely expanded flukes, and
perpendicularly into the depths of the ocean
Those in the boats, however, having noticed
proceeded onwards, thinking the whale would
o pursue the same direction under water;
was going slowly at the time he was up, they
roceed more than a mile from the place
e descended, before they separated about a
ards from each other, and their 'peaking'
, all the men in each boat stood up, looking
t directions, so as to catch the first appear-
spout when the whale again rose to breathe:
our after his descent had expired, the excite-
ng us who were on board the ship became
to its highest pitch. The captain, who had
on board, ascended to the fore-top-gallant-
atch the manœuvres of the boats, and for the
f the better ordering the signals to them, or

were lost. The mischief has progressively increased. In 1837, the Davis' Straits whale-fleet lost several of its number, and many vessels were locked up in the ice through the winter, to the loss of the greater part of their crews, and at the cost of almost unparalleled sufferings to the petty remnants of them which escaped with life. And while the perils of the trade have thus largely increased, the profits, owing to the greater difficulty of finding whales, have suffered a corresponding decrease. In 1830, 24 out of the 87 vessels sent out to Davis' Straits, returned *clean*. Not a fish was taken by them. In the most of the years that have followed, the majority of the whalers have returned with comparatively paltry freights, and many without a pound of blubber.

The declension, and apparent approaching extinction of the northern whale-fishing, which has so long been an important pillar of our commercial greatness, could not but excite uneasiness and regret in the minds of many persons who have opportunities of making observations on the subject. Accordingly, we find that various plans have been proposed for the revival of this branch of the trade of Britain. Although we conceive that the substitution of gas for oil is one important cause of the decreased ardour for whaling enterprises, and a cause, besides, neither to be deplored nor capable of remedy, and although it also appears to us that the exhaustion of the old whaling fields is another source of the evils complained of, and one only to be affected by time, yet there might, we believe, be plans adopted, which would help at once to restore the lucrative character of the whale fishery, and to alleviate or entirely prevent the misfortunes which have attended its prosecution of late years. The most rational scheme which we have yet chanced to see proposed, is contained in the following extract from the Aberdeen Herald :—

"The plan is simply to establish a settlement of active and enterprising whale fishers on some favourable spot in the vicinity of Davis' Straits, and to employ only so many large vessels as may be necessary to carry out provisions to the colony, and fetch home the oil, blubber, whalebone, and other articles which may be thought worth importing. From all the information that we at present possess, we should think that the most eligible position for the settlement would be at Pond's Bay, or somewhere between that and Lancaster Sound, on the west coast of Baffin's Bay. There are some situations on the north-east shore (Prince Regent's Bay, for example) that might be found suitable; but of late years, the fishers assert that the whales have been most plentiful towards the other shore.

The practicability of carrying such a plan into effect, and the advantages likely to result from it, are the only two points that fall to be noticed here. The testimony of recent travellers, as well as of seamen who have been compelled to winter in the high latitudes, goes to prove the practicability of establishing and maintaining an efficient colony, even as far north as the place we have pointed out. Captain Ross's remark, that 'the temperature of sensation is more relative than is imagined, the body soon contriving to find a new and much lower scale of comfortable or endurable heat,' has been completely verified by all who have visited the Polar regions. The attention now paid to the quality of ship provisions, and the improved methods of preserving them, have not only put a stop to the inroads of scurvy, but have tended materially to increase the comfort of those who choose to lengthen their stay in cold countries. In East Greenland there are several Danish settlements. Holsteinberg, within the Arctic circle, is a small town, with a church and a clergyman; and still higher up, at Lievly, in Disco Island, the chief Danish governor resides. With an ample store of food and clothing, and materials for constructing houses, there can be no doubt that a colony of hardy whalers would contrive to pass the winter agreeably and in comfort. Nor would they be dependent altogether on the supplies carried with them, or procured from the mother country. The musk ox, the reindeer, the white bear, the hare, and a number of other quad would afford them at once sport and a valuable a to their means of sustenance. Birds, too, an fish of various kinds, would not be wanting variety to their repasts; while lobsters, musse other shell-fish, could be had as abundantly as a To avoid all risks of famine, it would be proper always in the settlement provisions for two yea though it could hardly ever happen that the settler be so completely shut up as to be inaccessible dur whole of the summer months.

The advantages of having a numerous body of on the spot, instead of sending them out annual easily be made apparent. 1st, There would be of outlaid capital. For some time past, the shi from Great Britain to Davis' Straits may ha raged 100 each year; and we believe we speak limits when we assert, that the oil and whalebon they have brought home might easily have be ried by one-fifth of the number. Suppose a per colony of 4000 fishers were established at Davis' and 20 of the 100 vessels employed in the o trade, the other 80 vessels might at once be with making a saving of out-laid capital to the exte least £320,000. In this calculation, we take mer cost of the ships, as the boats, harpoons, cas other apparatus, and the provisions included outfit, would all be required in the settlement. fishery would have a better chance of being suc At present it sometimes happens that vessels can into the proper fishing station till the season is advanced that they are under the necessity of ret home without lowering their boats, and this di arises not from the want of open sea within the but from accumulations of ice drifted from the extremity of Baffin's Bay to the Labrador coa settlement of fishers wintering inside, would i cases make a good fishing before the British shi penetrated far up the Straits."

SPERM-WHALE FISHERY.

It is now our purpose to devote some space proceedings in the sperm-whale fishery, a bra maritime enterprise only inferior in importance northern fishery. There is no occasion for des the vessels or apparatus employed, these being in every essential point to those already des Timid as it is, the cachalot often causes such p its convulsive efforts to escape, as render its captu less exciting than that of the mysticetus. Young in particular, frequently give a world of trou their pursuers, and sometimes turn upon them unbounded fury, intent on mischief, and effec both with teeth and tail. The South Sea whaler their northern brethren, have their particular and watchwords in the prosecution of the chase. a whale is seen by the man at the look-out, th bursts from his lips, "There she spouts!" Ins the captain starts on deck, with the responsive mation, "Where away?" An answer is scarcely n for all on board soon perceive the huge animal, ing regularly at intervals of ten seconds, if wi moderate distance. For a half-minute the men gazing, and at every spout the spirited cry breaks from them simultaneously, "There again!" Bu ness is not long the order of the day. The boa lowered, the men rush into them, and soon are p towards the monster, every boat eager to reac first. As they approach, they see him spouting slowly. "Ah, he is going down!—he will be lo is the exclamation. But one boat nears him. more spout (says Mr Beale's animated narrati seen slowly curling forth—it is his last for this ri his back is bent, his enormous tail is expected pear every instant, but the boat shoots rapidly side of the gigantic creature. working of the ship. All those who were down after the whale, appeared as feverish with anxiety as ourselves, for every now and then they were to be seen shifting their positions a little, thinking to do so with advantage; then they would cease rowing, and stand upon the seats of the boats, and look all round over the smooth surface of the ocean with ardent gaze. But one hour and ten minutes expired before the monster of the deep thought proper to break cover; and when he did, then a rattling chase commenced with the whole of the boats, and they really flew along in fine style, some of them actually appearing to be lifted quite on the surface of the water, from the great power of the rowers; and we had the satisfaction of observing, that our boats were quite equal to the others in the speed with which they were propelled. But it was again a useless task, as the old 'schoolmaster' had outwitted those in the boats, by having gone—while under water—much farther than any of his pursuers had anticipated, and they again had the mortification of witnessing the turning of his flukes as he once more descended into the depths of his vast domain. We now knew to a minute the time that he would remain below, while the people in the boats continued to row slowly onwards the whole time. A fine breeze now sprang up, so that we were enabled to keep company with the boats, keeping a little to windward of them, as the whale was going 'on a wind,' as a seaman would say, meaning that it was blowing across him.

When the hour and ten minutes had again nearly passed, the nine boats were nearly abreast of each other, and not much separated, so that the success of first striking the whale depended very much upon the swiftest boat, especially if the whale came up ahead. We had now all the boats on our 'lee-beam,' while the ships were all astern of us, the most distant not being more than half a mile, so that we enjoyed an excellent view of this most exciting and animated scene. True to his time, the leviathan at length arose right ahead of the boats, and at not more than a quarter of a mile distant from them. The excitement among the crews of the various boats when they saw his first spout was tremendous; they did not shout, but we could hear an agitated murmur from their united voices reverberating along the surface of the deep. They flew over the limpid waves at a rapid rate; the mates of the various boats cheered their respective crews by various urgent exclamations, 'Swing on your oars, my boys, for the honour of the Henrietta,' cried one; 'Spring away, hearties,' shouted another, and yet scarcely able to breathe from anxiety and exertion. 'It's our fish,' vociferated a third, as he passed the rest of his opponents but a trifling distance. 'Lay on, my boys,' cried young Clark, our first mate, as he steered the boat with one hand, and pressed down the after oar with the other. 'She'll be ours yet; let's have a strong pull, a long pull, and a pull altogether,' he exclaimed, as he panted from his exertions at the after oar, which soon brought up his boat quite abreast of the foremost.

But the giant of the ocean, who was only a short distance before them, now appeared rather 'gallied,' or frightened, having probably seen or heard the boats; and as he puffed up his spout to a great height, and reared his enormous head, he increased his speed, and went along quite as fast as the boats, but for only two or three minutes, when he appeared to get perfectly quiet again, while the boats gained rapidly upon him, and were soon close in his 'wake.' 'Stand up,' cried young Clark to the harpooner, who is also the bow-oarsman, while the same order was instantly given by his opponent, whose boat was abreast of our mate's, with the rest close to their sterns. The orders were instantly obeyed, for in a second of time both boat-steerers stood in the bows of their respective boats, with their harpoons held above their heads ready for the dart; but they both panted to be a few yards nearer to the whale, to do so with success. The monster ploughed through the main quickly, but the boats gained upon him every moment, when the agitation of all parties became intense, and a general cry of 'dart! dart from the hindmost boats, who each urged their fearful of delay. The uproar became excessi while the tumult of voices, and the working and ing of the oars, rolled along the surface of t both the harpooners darted their weapons t which, if they had both struck the whale, wo originated a contention between them regardi claims. But, as it happened, neither of them good fortune; for at the moment of their dar harpoons, the whale descended like a shot, and their infliction, leaving nothing but a white-an looking-vortex in the disturbed blue ocean, to spot where his monstrous form so lately floated. huzza burst from the sternmost boats when the issue of this chase, thinking now that anothe awaited them on the next rising of the whale, soon began to separate themselves a little, an onwards again in the course which they though taken. Our captain, feeling irritated at the il of the mate, now ordered his own boat to be intending to make one in the chase himself; as he had parted from the ship, going down leeward, a tremendous shout arose from the our own boats, joined with a loud murmuring rest of the boats' crews; for the whale, no had all its 'spoutings out,' had now risen finish them, and was coming to windward at rate, right towards our ship. The captain favourable situation in a moment, and, passing to the bows of the boat, he stood to waylay h came careering along, throwing his enorm completely out of the water, for he was now q lied.' He soon came, and caught a sight of just as he got within dart; the vast animal rol over in an agony of fear, to alter its course; b too late; the harpoon was hurled with excell and was plunged deeply into his side near the

As the immense creature almost flew out of t from the blow, throwing tons of spray high int showing that he was 'fast,' a triumphant cheer from those in our own boats, as well as from the ship, accompanied by exclamations loud a and not of the most favourable kind to us, fro rest. But onwards they all came, and soon el rendered assistance to complete its destruct which was not done, however, without con difficulty, the whale continuing to descend the either of the boats got nearly within dart of hi after an hour's exertion in this way, six out of boats which were now engaged, got fast to him harpoons, but not one of them could get near to give him a fatal lance; he towed them all in directions for some time, taking care to descen the surface the moment a boat drew up over hi or otherwise drew near, which rendered it alm possible to strike him in the body, even when t was darted, although the after part of his 'sm perforated in a hundred places: from these wo blood gushed in considerable quantities, and as t animal moved along, towing the boats, he left ensanguined stain in the ocean. At last, becomi from his numerous and deep wounds, he beca capable of avoiding his foes, which gave an opp for one of them to pierce him to the life. Dres that moment the acute pain which the leviatha rienced, and which roused the dormant energie gigantic frame. As the life's blood gurgled thick the nostril, the immense creature went into his with excessive fury; the boats were speedily ste while he beat the water in his dying convulsi a force that appeared to shake the firm found the ocean!"

CONCLUDING ANECDOTES AND OBSERVATIONS

Mr Beale continues to remark, in his narrat "numberless stories are told of fighting whale of which, however, are probably much exa accounts of the real occurrences. A large whal

mor Jack,' is the hero of many strange stories, such of his destroying every boat which was sent out inst him, until a contrivance was made by lashing arrel to the end of the harpoon with which he was uck, and whilst his attention was directed and divided ongst several boats, means were found of giving him death-wound.

In the year 1804, the ship 'Adonis,' being in comny with several others, struck a large whale off the st of New Zealand, which 'stove' or destroyed nine ats before breakfast, and the chase consequently was essarily given up. After destroying boats belonging many ships, this whale was at last captured, and ny harpoons of the various ships that had from time time been sent out against him were found sticking his body. This whale was called 'New Zealand Tom,' d the tradition is carefully preserved by whalers.

Accidents of the most fearful nature have frequently urred in this hazardous pursuit, which to enumerate uld fill the space of volumes; for not only boats, but metimes even ships, have been destroyed by these werful creatures. It is a well authenticated fact, at an American whale-ship called the 'Essex' was stroyed in the South Pacific Ocean by an enormous erm whale. While the greater part of the crew were ay in the boats pursuing whales, the few people reining on board saw an immense sperm whale come close to the ship, and when very near, he appeared go down for the purpose of avoiding the vessel, and doing so he struck his body against some part of the el, which was broken off by the force of the blow, and ated to the surface; the whale was then observed to e a short distance from the ship, and come with aprently great fury towards it, striking against one of bows with his head, and completely 'staving' it in. e ship of course immediately filled, and fell over on r side, in which dreadful position the poor fellows in boats soon espied their only home, being distant m the nearest land many hundred miles; on returng to the wreck, they found the few who had been left board hastily congregated in a remaining whale-boat, o which they had scarcely time to take refuge before e vessel capsized. They with much difficulty obtained scanty supply of provisions from the wreck, their only pport on the long and dreary passage before them the coast of Peru, to which they endeavoured to ake the best of their way. One boat was fortunately und by a vessel not far from the coast; in it were the ly survivors of the unfortunate crew, three in number, the remainder having perished under unheard-of ffering and privation. These three men were in a ate of stupefaction, allowing their boat to drift about here the winds and waves listed; one of these survors was the master; by kind and careful attention n the part of their deliverers, they were eventually atched from the jaws of death to relate the melancholy le."

Not being attended with the dangers to which a orthern climate exposes the hunters of the mysticetus, he sperm-whalers of Britain have greatly increased in mbers of late years, and at this day the fishing is xecuted with great success. As in the case of the reenland fishery, bounties were given up to 1821, hen the trade was fairly left to private enterprise. n 1791, the sperm-oil imported into Britain amounted 1258 tons; in 1827, 5552 tons were imported; and 1836, the amount was 7001 tons. One good whale will ld forty barrels of oil, and ten barrels of spermaceti e frequently taken from one head. About ten large rrels make a ton. Both sperm-oil and spermaceti ar a high price in the market, and are of great utility various respects. There is little chance of a decline the sperm-whale branch of our maritime traffic, not ly because the fishing latitudes are comparatively e from dangers, but because the invention of gas s not trench on the use of sperm-oil as it did on that the Greenland oil, and because spermaceti and rm oil are likely to be more and more employed as country progresses in civilisation.

FOREIGN WHALE-FISHERIES.

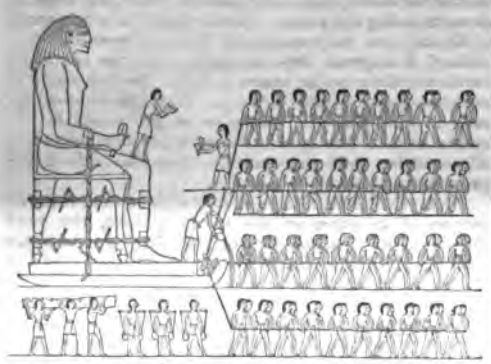
The whale-fisheries of other civilised nations have undergone as great vicissitudes as those of Britain. About the year 1680, the Dutch sent out not less than 260 ships, manned by 14,000 men, to the northern fishery. In 1828, only one whale-ship sailed from Holland! France has never prosecuted this branch of commerce with much activity or success, yet the little that was once done in this way has become still less. In 1790, 40 French ships were employed in the Greenland seas. The revolution put a stop to the fishing, and though of late years the government has made an attempt to revive it, very little success has resulted.

The people of the United States have been more active and successful in whale-fishing than almost any other nation in recent days. While dependent colonists, they embarked in it with great spirit. From 1771 to 1775, Massachusetts employed annually 183 vessels, of 13,820 tons, in the northern fishery; and 121 vessels, of 14,026 tons, in the fisheries of the south. They were the first to prosecute the trade in the southern Atlantic, on the coasts of Africa and Brazil; and they, too, led the way into the Pacific seas:—"Look at the manner," says Burke (1774), "in which the New England people carry on the whale fishery. While we follow them among the tumbling mountains of ice, and behold them penetrating into the deepest frozen recesses of Hudson's Bay and Davis' Straits; while we are looking for them beneath the Arctic circle, we hear that they have pierced into the opposite region of polar cold; that they are at the antipodes, and engaged under the frozen serpent of the south. Falkland Island, which seemed too remote and too romantic an object for the grasp of national ambition, is but a stage and resting-place for their victorious industry. Nor is the equinoctial heat more discouraging to them than the accumulated winter of both the poles. We learn that, while some of them draw the line or strike the harpoon on the coast of Africa, others run the longitude, and pursue their gigantic game along the coast of Brazil." These are the seas that are still vexed by the American fisheries, which have been pushed, however, into higher southern latitudes than had ever before been visited, and are carried on from the shores of Japan to the icy rocks of New South Shetland. They have been principally carried on from Nantucket and New Bedford, and have proved very lucrative. At present they are also prosecuted with great success from several other places. One class of ships is fitted out for the Pacific in pursuit of the spermaceti whale. These are from 300 to 500 tons burden, carrying from 25 to 30 men, and are absent about 30 to 36 months. Their number is about 170, of about 62,000 tons, and carrying nearly 5000 men. Another class sail to the coasts of Africa and Brazil, in search of the common or right whale. They average about 325 tons each, carry about 25 men, and are absent 8 to 12 months. The whole amount of tonnage of this class is about 40,000; number of seamen engaged, 3000. The quantity of sperm oil brought home in 1815, was 3944 barrels; in 1820, 34,700; in 1825, 62,240; and, in 1830, 106,800. The quantity of whale or black oil brought in in 1830, was about 115,000 barrels; of whalebone, about 120,000 pounds. The sperm oil is chiefly used at home; and 2,500,000 pounds of sperm candles are made, employing about 30 manufactories. The whale oil and whalebone are chiefly exported to Europe. From the report of the secretary of the treasury, May 4, 1832, it appears that for the year ending September 30, 1831, there were exported whale and other fish oil to the value of 554,440 dollars; spermaceti oil to the value of 53,526 dollars; whalebone to the value of 133,842 dollars; and spermaceti candles to the value of 217,830 dollars.

Of the extent of the sufferings sometimes experienced by the whalers, a single example may be given. The Dee, an Aberdeen whaler, sailed for Davis' Straits in April 1836, and, after many difficulties, was ultimately fast locked up in the ice, in October of the same year,

a sort of umbrella, fixed upon a rod rising from the centre or back of the car; the reins were the same as those used for horses, and apparently furnished with a bit; and besides the driver, a groom sometimes attended on foot, at the head of the animals, perhaps feeding them as they went. The annexed wood engraving represents an Ethiopian princess, who is on her journey through Upper Egypt to Thebes, where the court then resided. The plaustra are called in Genesis *waggons;* they were commonly used in Egypt for travelling. Besides the plaustrum, they had a sort of palanquin, and a canopy or framework, answering the purpose of a sedan-chair, in which they sometimes sat or stood, in their open pleasure-boats, or in situations where they wished to avoid the sun."

From the researches of Mr Wilkinson, we are enabled to form some estimate of the enormous trouble incurred by the ancient Egyptians in the transport of the heavy stones which they employed in building their temples. Some of these stones weighed 5000 tons, and were usually conveyed from the quarries from which they were cut in flat-bottomed boats, on canals made for the purpose. Occasionally, however, when this mode of transport was unsuitable, the stone was drawn on sledges, perhaps some hundreds of miles, by oxen or by human labour. The accompanying woodcut represents, in an abridged form, the mode of conveying colossal figures in stone from the quarries to the temples in which they were to be set up. "One hundred and seventy-two men,



in four rows of forty-three each [we represent only as far as twenty each row], pull the ropes attached to the front of the sledge; and a liquid, probably grease, is poured from a vase by a person standing on the pedestal of the statue, in order to facilitate its progress as it slides over the ground, which was probably covered with a bed of planks, though they are not indicated in the painting. Some of the persons employed in this laborious duty appear to be Egyptians, the others are foreign slaves, who are clad in the costume of their country. Below are persons carrying vases of the liquid, or perhaps water, for the use of the workmen, and some implements connected with the transport of the statue, followed by taskmasters with their wands of office [but which we have not had space to include]. On the knee of the figure stands a man who claps his hands to the measured cadence of a song, to mark the time, and ensure their simultaneous draught. The height of the statue appears to have been about twenty-four feet, including the pedestal. It was bound to the sledge by ropes, which were tightened by means of pegs inserted between them, and twisted round until completely braced; and to prevent injury from the friction of the ropes upon the stone, a compress of leather or other substance was introduced at the part *where they* touched the statue." It may be added, that *the representation is* constructed without any reference *to perspective, which* was not understood by the ancient *Egyptian delineators.* Besides the great number of persons employed in drawing these huge blocks, it was customary for a band of some hundreds of soldiers to attend, perhaps for the purpose of overawing the and compelling obedience to their odious task. A degrading means of mechanical conveyance it we impossible to represent.

Conveyance by Camels.—From the earliest tim camel, in its two varieties of camel and drome has been employed in the sandy regions of As beast of burden; and without its invaluable serv this respect, these countries could scarcely hav habitable. In the sacred writings we find fr notices of the camel in connexion with comm transport. The brethren of Joseph having ca into a pit, "they sat down to eat bread; an lifted up their eyes and looked, and behold a co of Ishmaelites came from Gilead, with their bearing spicery, and balm, and myrrh, going to it down into Egypt." Thus the camel forme engine of carriage among the merchants of A and conveyed the products of India across the d to the populous and wealthy land of Egypt.

The camel is expressly suited by nature for in ing and traversing sandy and parched deserts, in there are places of rest and refreshment only at r distances. "It is the most temperate of all an and can continue to travel several days without ing. In those vast deserts, where the earth is where dry and sandy—where there are neither nor beasts, neither insects nor vegetables—whe thing is to be seen but hills of sand and hea bones, there the camel travels, posting forward, out requiring either drink or pasture, and is often six or seven days without any sustenance whats Its feet are formed for travelling upon sand, and u unfit for moist or marshy places; the inhabitants, fore, find a most useful assistant in this animal, no other could subsist, and by its means, cross deserts with safety, which would be impassable b other method of conveyance.

An animal thus formed for a sandy and dese gion, cannot be propagated in one of a different n Many vain efforts have been tried to propaga camel in Spain and America, but they have mult in neither of these countries. It is true, indeed they may be brought into both countries, and perhaps be found to produce there; but the ex keeping them is so great, and the accidents to they are exposed, from the changeableness of th mate, are so many, that they do not reward the e keeping. In a few years, also, they are seen to nerate; their strength and their patience forsake and, instead of making the riches, they become th den of their keepers.

The camel is easily instructed in the methods ing up and supporting his burden; their legs, days after they are produced, are bent under their they are in this manner loaded, and taught to rise burden is every day thus increased, by insensi grees, till the animal is capable of supporting a adequate to its force. The same care is taken in ing them patient of hunger and thirst: while animals receive their food at stated times, the ca restrained for days together, and these intervals mine are increased in proportion as the animal capable of sustaining them. By this method of tion, they live five or six days without food or and their stomach is formed most admirably by to fit them for long abstinence. Besides the stomachs which all animals have that chew th (and the camel is of the number), it has a fifth sto which serves as a reservoir to hold a greater qu of water than the animal has an immediate oc for. It is of a sufficient capacity to contain a quantity of water, where the fluid remains without rupting, or without being adulterated by the oth ments: when the camel finds itself pressed with

* The only essential difference between the two varie that the camel has two hunches and the dromedary o there are mixed breeds between them.

NCE.

, strewed with flowers, and thick with pasture for
camels, where we are now resting. It is not usual
re, as in many parts of the east, for the camels to
nd in long strings, one after the other. Our numbers,
mounting to fifteen hundred, are scattered over the
rface in all directions, as far as the eye can trace.
In travelling, the sheiks or chiefs of the caravan,
ended by the military part of their equipage, mounted
dromedaries, move in advance, while the loaded
mels follow at some distance, in parallel masses,
ening out, or changing the form, as the grass ren-
rs it necessary. They fall so naturally into military
ares, that it is difficult to conceive their doing it
thout direction.
We have several tents in the caravan. They are
ched so as to permit the camels belonging to each to
in the intervals, where they are placed in squads for
e night. They are by no means agreeable neighbours;
, although they are not able to move from their
ce, they make a most unpleasant gurgling noise: the
les of the merchants always form the windward de-
nce, for the tents have no sides to them, and but
tter over the goods to keep the sun from their
ners.
At the usual hours of prayer, a loud call is heard
roughout the camp, and parties flock to where the
nezzin takes his stand. At sunset, as the camels
aw in from the pasture, all the Arabs are on their
ees, in a line of two or three hundred, in two ranks.
he priest, like a fugleman, in front, gives the time for
wing their heads, and performing the rest of the
joined ceremonies. As they rise on the signal, they
ik again to their knees, and press their foreheads to
e earth with the utmost devotion: the scene is sin-
larly impressive.
The rate at which a loaded camel travels is estimated
two miles and a-half an hour by almost every tra-
ller. Our caravan has not, I think, exceeded this;
t the variety of its movements has been very gre-
me. The Arab drivers, who walk in front of the
imals, never miss an opportunity of a piece of pasture;
t, however distant it may be from the proper course,
ad them towards it, and, with the short sticks they
rry, beat them into the thickest part of it. The
mels are anxious enough for the matter themselves,
d huddle so together that their riders' legs are in
derable danger of being crushed in the contact.
There is so strong a resemblance to a voyage at sea
a passage across the desert, that I cannot divest
yself of the belief that the moving mass is but a col-
ction of small vessels, carried into a heap by the tide.
very man is ready with his stick to fend off the ani-
al that approaches him; one push separates the
mels as it would separate a couple of boats; and the
mels move away, quite unconscious of the circum-
ance, till another movement swings them together
gain."

TRAVELLING IN PAST TIMES IN BRITAIN.

The modes of travelling and conveyance generally,
ere of a comparatively rude and primitive kind in
ritain till the latter part of the seventeenth century;
nd any thing like comfortable and quick travelling
annot be said to have been known till a century later,
hen mail-coaching was introduced. In old times,
eople of a humble rank travelled only on foot, and
hose of a higher station on horseback. Noblemen and
entlemen, as much for ostentation as use, kept run-
ing footmen—a class of servants active in limb, who
an before them on a journey, or went upon errands
f special import. The pedestrian powers of these fel-
ows were often surprising. For instance, in the Duke
f Lauderdale's house at Thirlstane, near Lauder,
he table-cloth being one morning laid for a
dinner-party, it was discovered that there was a

little piece of ground, which to this day bears the name of the *Post Rig*—a term equivalent to the postman's field, and an unquestionable proof, as all the villagers at Hume devoutly believe, of the truth of the anecdote. The custom of keeping a running footman did not cease amongst noble families in Scotland till the middle of the last century. The Earl of March, father to the late Duke of Queensberry, and who lived at Neidpath Castle near Peebles, had one named John Mann, who used to run in front of the carriage, with a long staff. In the head of the staff there was a recess for a hard-boiled egg, such being the only food taken by Mann during a long journey.

When the matter of communication was of particular importance, or required to be dispatched to a considerable distance, horsemen were employed; and these, by means of relays of fresh animals and great toil of body, would proceed journeys of some hundreds of miles to accomplish what would now be much better done by a post letter. Some journeys performed on horseback in former days would be considered wonderful even in modern times with good roads. Queen Elizabeth died at one o'clock of the morning of Thursday the 24th of March 1603. Between nine and ten, Sir Robert Carey left London (after having been up all night), for the purpose of conveying the intelligence to her successor James, at Edinburgh. That night he rode to Doncaster, a hundred and fifty-five miles. Next night he reached Witherington, near Morpeth. Early on Saturday morning he proceeded by Norham across the Border; and that evening, at no late hour, kneeled beside the king's bed at Holyrood, and saluted him as King of England, France, and Ireland. He had thus travelled four hundred miles in three days, resting during the two intermediate nights. But it must not be supposed that speed like this was attained on all occasions. At the commencement of the religious troubles in the reign of Charles I., when matters of the utmost importance were debated between the king and his northern subjects, it uniformly appears that a communication from Edinburgh to London, however pressing might be the occasion, was not answered in less than a fortnight. The crowds of nobles, clergymen, gentlemen, and burghers, who at that time assembled in Edinburgh to concert measures for opposing the

, confined chiefly to the great lines of road in Eng-
l. On all the less important routes, and particularly
Scotland, the only means of conveyance for goods
by pack-horses. These animals were loaded with

ks thrown across the back; and, if not too heavy,
d to a considerable height. A number together
re generally conducted in a line along the narrow
l badly constructed paths, that which went before
rying a bell, by the tinkling sound of which the
cade was kept from straggling after nightfall. This
eedingly rude mode of conveyance continued in
ration in some parts of the country till the year
0, or thereabouts, when one-horse carts came into
.

The old-fashioned waggons still remain in use in
gland, notwithstanding the numerous improvements
modes of conveyance and locomotion. They are
efly employed for the carriage of goods between the
tropolis and country towns which are at a distance
m any line of canal or railroad. A waggon of this
d is provided with four broad and huge wheels, and
drawn by six large horses, the driver usually riding
a separate small pony. The waggons employed in

ndon to convey coal from the wharfs to the houses
consumers, or beer from brewers, are of the same
wieldy form, and are drawn with a needless expen-
ture of power.

The length of time consumed in journeys by even
e best kind of carriages of past times, is now matter
r surprise. The stage-coach which went between
ndon and Oxford in the reign of Charles II., re-
ired two days, though the space is only fifty-eight
les. That to Exeter (168¼ miles) required four days.
1703, when Prince George of Denmark went from
indsor to Petworth to meet Charles III. of Spain,
e distance being about forty miles, he required four-
en hours for the journey, the last nine miles taking
x. The person who records this fact, says, that the
ng time was the more surprising, as, *except when
erturned*, or when stuck fast in the mire, his royal
ghness made no stop during the journey.

In 1742, stage-coaches must have been more nume-
us in England than in Charles II.'s time; but it does
t appear that they moved any faster. The journey
om London to Birmingham (116 miles) then occupied
arly three days, as appears from the following adver-
sement:—"The Litchfield and Birmingham stage-
oach set out this morning (Monday, April 12, 1742),
om the Rose Inn, Holborn Bridge, London, and will
e at the Angel, and the Hen and Chickens, in the
igh Town, Birmingham, on Wednesday next, to dine
er; and goes the same afternoon to Litchfield."

ciency of silver spoons. Instantly the footman was sent off to the duke's other seat of Lethington, near Haddington, fully seventeen miles off, and across hills and moors, for a supply of the necessary article. He returned with a bundle of spoons, in time for dinner. Again—at Hume Castle in Berwickshire, the Earl of Home had one night given his footman a commission to proceed to Edinburgh (thirty-five miles off), in order to deliver a message of high political consequence. Next morning early, when his lordship entered the hall, he saw the man sleeping on a bench, and conceiving that he had neglected his duty, was about to commit some rash act, when the poor fellow awoke, and informed Lord Home that his commission had been executed, and that, having returned before his lordship was stirring, he had only taken leave to rest himself a little. The earl, equally astonished and gratified by the activity of his faithful vassal, rewarded him with a little piece of ground, which to this day bears the name of the *Post Rig*—a term equivalent to the post-man's field, and an unquestionable proof, as all the villagers at Hume devoutly believe, of the truth of the anecdote. The custom of keeping a running footman did not cease amongst noble families in Scotland till the middle of the last century. The Earl of March, father to the late Duke of Queensberry, and who lived at Neidpath Castle near Peebles, had one named John Mann, who used to run in front of the carriage, with a long staff. In the head of the staff there was a recess for a hard-boiled egg, such being the only food taken by Mann during a long journey.

When the matter of communication was of particular importance, or required to be dispatched to a considerable distance, horsemen were employed; and these, by means of relays of fresh animals and great toil of body, would proceed journeys of some hundreds of miles to accomplish what would now be much better done by a post letter. Some journeys performed on horseback in former days would be considered wonderful even in modern times with good roads. Queen Elizabeth died at one o'clock of the morning of Thursday the 24th of March 1603. Between nine and ten, Sir Robert Carey left London (after having been up all night), for the purpose of conveying the intelligence to her successor James, at Edinburgh. That night he rode to Doncaster, a hundred and fifty-five miles. Next night he reached Witherington, near Morpeth. Early on Saturday morning he proceeded by Norham across the Border; and that evening, at no late hour, kneeled beside the king's bed at Holyrood, and saluted him as King of England, France, and Ireland. He had thus travelled four hundred miles in three days, resting during the two intermediate nights. But it must not be supposed that speed like this was attained on all occasions. At the commencement of the religious troubles in the reign of Charles I., when matters of the utmost importance were debated between the king and his northern subjects, it uniformly appears that a communication from Edinburgh to London, however pressing might be the occasion, was not answered in less than a fortnight. The crowds of nobles, clergymen, gentlemen, and burghers, who at that time assembled in Edinburgh to concert measures for opposing the designs of the court, always dispersed back to their homes after dispatching a message to King Charles, and assembled again a fortnight thereafter, in order to receive the reply, and take such measures as it might call for. And even till the last century was pretty far advanced, the ordinary riding post between London and Edinburgh regularly took a week to the journey.

In consequence of the inattention of our ancestors to roads, and the wretched state in which these were usually kept, it was long before coaching of any kind came much into fashion. Though wheeled vehicles of various kinds were in use among the ancients, the close carriage or coach is of modern invention. The word *coach* is Hungarian, and the vehicle itself is supposed to have originated in Hungary. Germany certainly appears to have taken the precedence of the nations of Western Europe in using coaches. They were introduced thence into England some time in the sixteenth century, but were, after all, so little in vogue throughout the whole reign of Elizabeth, that there is record of her having ever used one. Lord Grey de Wilton, who died in 1593, introduced a coach into Ireland, the first ever used in that country. One was introduced into Scotland—we rather think from France—about the year 1571. It belonged to the famous Secretary Maitland of Lethington, who, during the horrid civil war between the adherents of Mary and those of her son James, made a journey in that vehicle from Edinburgh Castle, which he was holding out for the queen, to Linlithgow in West Lothian, for the purpose of holding a consultation with some others of her friends—the only time, it is believed, that a close carriage was ever seen in Scotland. Fynes Morison, who wrote in the year 1617, speaks of coaches as recently introduced, and still rare in Scotland. For a long time, these conveyances were only used by old people, who could not ride on riding. The young and active despised them, according to effeminacy, and as not being so quick of movement as the horse. The Duke of Buckingham, who first used a coach with six horses—a piece of state which the Duke of Northumberland thought proper to ridicule by setting up one with eight. Charles I. was the first British sovereign who had a state coach. Although Henri IV. was killed in a coach—the only one, by the way, he possessed—his ordinary way of appearing in the streets of Paris was on horseback, with a large cloak strapped on behind, to be used in case of rain. In Scotland, previous to the time of the civil war, coaches were only used by persons high in state. It is very curious to find that the same kind of complaints now made by persons interested in opposing respecting the introduction of steam-locomotives were made when coaches were introduced. Taylor, the water-poet, complains, in the reign of Charles I., that large retinues of men were now given up by the nobility since they had begun to use coaches. Ten, twenty, thirty, fifty, yea a hundred proper serving men, were transformed, he says, into two or three animals. The old-wifical thinkers of that day were as much concerned about the fate of the discharged men-servants, as twaddlers of the present are distressed about the fate of less horses. It is further very amusing to find Taylor in his antipathy to coaches, complaining that coach-drivers were all of them hard drinkers.

In a pamphlet called the "Grand Concern of England Explained," published in 1673, the writer gravely attempts to make out that the introduction of coaches was ruining the trade of England. The following is an example of his mode of reasoning: "Before the coaches were set up, travellers rode on horseback, and men had boots, spurs, saddles, bridles, saddle-cloths, and good riding-suits, coats and cloaks, stockings and hats, whereby the wool and leather of the kingdom were consumed. Besides, most gentlemen when they travelled on horseback used to be with swords, belts, pistols, holsters, portmanteaus, and hat-cases, which in these coaches they have little occasion for. For when they rode on horseback they rode in one suit, and carried another to wear when they came to their journey's end, or lay by the way; but in coaches they ride in a silk suit, with an embroidered gown, with a sash, silk stockings, and the beaver that men ride in, and carry no other with them. Besides, because they escape the wet and dirt which on horseback they cannot avoid; whereas in two or three journeys on horseback, these clothes and hats were quite ruined, to be spoiled; which done, they were forced to buy new very often, and that increased the consumption of manufacture. If they were women that travelled, they used to have safeguards and hoods, side-saddles and pillions, with strappings, saddle or pillion cloths, which, for the most part, were laced and embroidered; to the making of which there went many several trades, now ruined." But the writer has other reasons against coach travelling. "Those who travel

observes, "become weary and listless when
few miles, unwilling to get on horseback,
to endure frost, snow, or rain, or to lodge
." Besides, he asks "what advantage it
man's health to be called out of bed into
s an hour or two before day in the morn-
urried in them from place to place till one,
e hours within night; insomuch that, after
ay, in the summer time, stifled with heat
with dust—or in the winter time, starving
with cold, or choked with filthy fogs, they
ought into their inns by torch-light, when
to sit up to get supper, and next morning
ceed into the coach so early that they can
fast? What addition is it to men's health
to ride all day with strangers, oftentimes
, diseased persons, or young children cry-
se humours he is obliged to put up with,
poisoned with their nasty scents, and crippled
and bundles? Is it for a man's health *to
in the foul ways, and forced to wade up to
mire; afterwards* sit in the cold till teams
n be sent to pull the coach out? Is it for
to travel in rotten coaches, and to have
, or perch, or axle-tree broken; and then

e thought fit to introduce these extracts here,
ch for the purpose of amusing our readers
absurdity, as to afford a caution to the gene-
nts of improvement. Arguments of a simi-
l nature are now used in reference to almost
osed melioration in our social condition, and
less, in a century hence, be quoted for their
d folly, though at present meeting with coun-
m a large class in the community.

standing the introduction of stage-coaches in
eenth century, they were placed only on the
oads, and used almost exclusively by persons
taste and wealth. The popular mode of con-
ntinued for at least a century afterwards to
e-waggons; these were very large and cum-
achines, drawn by six or eight horses, and
iefly to the carriage of goods to and from
polis. The only part of the vehicle which
ccommodation to passengers, was the tail of
n, as it was called, a reserved space with a
cover at the hinder part of the machine; and
ng upon straw as they best could, some half-
sengers were slowly conveyed on their jour-
chance attacks of highwaymen, and other
hich occurred to the occupants of the waggon,
adventures at the inns where they slept for
are graphically described by Smollett in his
oderick Random, and will be in the recollec-
st of our readers.

ggons thus employed in the double office of
both goods and passengers, were, as we have said, confined chiefly to the great lines of road in England. On all the less important routes, and particularly in Scotland, the only means of conveyance for goods was by pack-horses. These animals were loaded with

sacks thrown across the back; and, if not too heavy, piled to a considerable height. A number together were generally conducted in a line along the narrow and badly constructed paths, that which went before carrying a bell, by the tinkling sound of which the cavalcade was kept from straggling after nightfall. This exceedingly rude mode of conveyance continued in operation in some parts of the country till the year 1780, or thereabouts, when one-horse carts came into use.

The old-fashioned waggons still remain in use in England, notwithstanding the numerous improvements in modes of conveyance and locomotion. They are chiefly employed for the carriage of goods between the metropolis and country towns which are at a distance from any line of canal or railroad. A waggon of this kind is provided with four broad and huge wheels, and is drawn by six large horses, the driver usually riding on a separate small pony. The waggons employed in

London to convey coal from the wharfs to the houses of consumers, or beer from brewers, are of the same unwieldy form, and are drawn with a needless expenditure of power.

The length of time consumed in journeys by even the best kind of carriages of past times, is now matter for surprise. The stage-coach which went between London and Oxford in the reign of Charles II., required two days, though the space is only fifty-eight miles. That to Exeter (168¼ miles) required four days. In 1703, when Prince George of Denmark went from Windsor to Petworth to meet Charles III. of Spain, the distance being about forty miles, he required fourteen hours for the journey, the last nine miles taking six. The person who records this fact, says, that the long time was the more surprising, as, *except when overturned*, or when stuck fast in the mire, his royal highness made no stop during the journey.

In 1742, stage-coaches must have been more numerous in England than in Charles II.'s time; but it does not appear that they moved any faster. The journey from London to Birmingham (116 miles) then occupied nearly three days, as appears from the following advertisement:—"The Litchfield and Birmingham stage-coach set out this morning (Monday, April 12, 1742), from the Rose Inn, Holborn Bridge, London, and will be at the Angel, and the Hen and Chickens, in the High Town, Birmingham, on Wednesday next, to dinner; and goes the same afternoon to Litchfield. It

to every ear—*Macadamised.*

In introducing this improvement into British roads, Mr M'Adam had spent several thousand pounds from his own resources. In 1825, he proved this expenditure before a committee of the House of Commons, when an equivalent sum was voted to him, besides an honorary tribute of two thousand pounds, in consideration of the public benefits resulting from his labours. The inadequacy of this remuneration is very striking; and it is impossible to avoid contrasting it, in some bitterness of spirit, with the ratio in which services of other and less beneficial kinds are usually acknowledged. Many a lieutenant, in being promoted to a captaincy for some little display of personal bravery, has reaped nearly as valuable a reward as that bestowed upon Mr M'Adam for bringing into operation a mechanical improvement, the consequences of which, in saving animal labour, facilitating commercial intercourse, and rendering travelling easy, quiet, and pleasant, are beyond all calculation. Though the remuneration was thus small, and never, as we have been informed, fully paid, Mr M'Adam would have been the last to complain of it. He never made money an object, but, on the contrary, rejected on principle many opportunities of gathering wealth, which his office as a superintendant opened up to him, and which many men of by no means blunt feelings as to professional propriety would have taken advantage of. He therefore died a poor, but, as he frequently expressed himself, "at least an honest man." Mr M'Adam's decease took place, November 26, 1836, at Moffat. He was in the 81st year of his age.

According to the principles of road-making, as laid down and consistently acted upon by Mr M'Adam, a road ought to be an artificial and hard flooring, placed on a level and dry surface. To make a good road, therefore, we must in the first place level and prepare the ground. If the ground be soft, as, for instance, have a covering of turf and earthy matter beneath, the top must be pared off, and as much earth removed as will produce a hardish base. In some instances, it may be necessary to excavate, and fill up the gap with compact and substantial materials; but should this be the case, the materials used must on no account include any large stones, or be otherwise unequal in their nature: The principles on which the road should be made are thus alluded to by Mr M'Adam:—"Roads can never be heavily loaded vehicle, but will sustain as and wear as any other portion of the highv

The width of the road is a matter of ta venience, but it should not be less than feet, to allow a free passage of vehicles directions. On all the good roads in Bi towns, a side footpath protected by a cu added to the ordinary breadth. "With re shape of the surface of the road, when comp is also some difference of opinion; but all it should be convex, the only difference b quantity. The degree of convexity should l in a great degree by the locality. A roa soft materials should have a greater convex formed of hard materials; for the obvious water will injure a soft road quicker than A road upon uneven ground should have a vexity than one upon level ground, to prev scent of rain-water along the face of the is there caught by the slightest impressions and thus wear channels, as may too often be the top to the bottom of the hill. A wid requires to be more crowning than a nar which more readily frees itself from rain-w much as the distance the water has to run i it must be borne in mind, that the freeing rain-water is not the only object to be kept making a road crowning. The ease and sa riages, and particularly those with heavy with high loads, must be consulted. A carr most freely, or with the least resistance, wh lies evenly upon the wheels. Just in propo weight or load is thrown on one side or the resistance is increased. Hence the inconve very crowning road on a steep; and hence t bars or breaks in long ascents. It is plain t should be equally and duly convex in every otherwise it becomes more partially worn level parts being most used.

When a road is carried round a hill inste directly over it, or when a road is made on it should not be made convex from the mi should be formed like half of a common ro highest part on the upper side, thus giving tendency to run off on the lower side. recommends the least possible convexity con

y as when accompanied with much traffic. The
ers on the surface, and softening the material,
on of the horses' feet and of the wheels causes
n depth of thin liquid mud. This mud should,
ssible, be scraped off to a side, for the longer it
e stratum beneath is the more liable to be cut
damaged. The scraping of the roads, therefore,
s an essential duty of all who are interested in
ing the highways economically in repair. When
d which is scraped aside thickens by exposure,
d be carted off, and may be employed on many
a useful manure. Besides containing a propor-
refuse from horses, it is loaded with particles
from wheels and horse shoes; and being sub-
ly silica or ground stone, it may be administered
ecial advantage to heavy clay grounds.
s exposed to much traffic require to be renewed
ace at least once a-year. The first indications
y are observable in the form of slight hollows,
s next make their appearance. In some cases,
the decay is only partial, a small quantity of
may be scattered in the hollows, bringing them
level with all around. However, this is not suf-
ie on well-kept roads near large towns. There
ld undergoes a thorough repair once a-year,
s preferable to partial mendings. The best time
airing roads is about November, or before the
frost and snow set in. In commencing the re-
e road should be picked across, at intervals of
or fifteen inches. This is done by men, each
a pick by which he indents the hard bottom,
s scores an inch deep in the road. The use of
preliminary process, is to cause a ready union
n the new and old materials. If the fresh metal
cattered over the old road, without any prepa-
it would with difficulty unite to the substratum,
best form an upper crust, which would be too
lamaged.
respect to the keeping of roads in efficient re-
e most advantageous plan consists in assigning
ire duty to a contractor. This person, by under-
to keep all the roads in a county or district
stant and uniform repair, is able to execute his
ns much more economically than the private
men who act as trustees of the highways and
ies. The trustees appointed by local acts of par-
t to superintend highways, now generally employ
ctors to keep the roads in repair at a specified
per mile, the payment being made from funds
d from the lessees of the toll-bars.
aggregate length of the turnpike roads of Great
n is now calculated to be 25,000 miles, at a gene-
adth of from fifty to sixty feet.* The cost of
g these roads in repair differs considerably in
nt counties. In the neighbourhood of London,
nual cost is about L.550 per mile, in Yorkshire
,69, and in Wales L.20. The average is about
Nearly all the road trusts are in debt for bor-
money. It is supposed that the debt is on an
e L.320 per mile, or probably L.6,000,000 for
ole.
of the Road.—For general convenience and safety,
s of vehicles and riders, in travelling along a road,
pected to take a particular side; and this practice
so well understood, and is in itself so proper, as
e become a part of the common law. The law
road is, that when drivers meet from different
ons, each shall keep his left hand to the wall or
h. Secondly, when one driver overtakes another,
shes to pass him, he must keep his left hand to
hicle which he passes. In the case of either
g or passing, each party is entitled to the half
road. The same rules apply to riders. If these
tions be neglected, and an accident occur, the

*pikes were so called from poles or bars, swung on a pivot,
been placed on them, and turned either way when duss
id. Gates are now substituted for these poles in Great
. In Germany, the pole is still used, one end being de-
to raise the other, and so permit a free passage.

law is always in favour of the party who kept his own proper side, and no excuse can shelter the aggressor. The trustees of the road are liable in an action of damages for any injury that may be sustained through the carelessness of themselves or servants, in leaving the road grossly out of repair.

According to a well-known rule, foot passengers on pavements or side-paths, are expected to walk with their right hand to the wall—that is, they keep their left hand to those whom they are meeting and passing. This custom prevents confusion in the streets of large towns, but is not a matter of law.

CANALS.

A canal is an artificial channel of water, and is usually constructed for inland navigation. Where natural rivers can be resorted to for purposes of this kind, they are preferable to canals, because little expense may be required to suit them for navigation, and they may be easily kept in repair. But few rivers, generally speaking, are sufficiently level, straight, or deep, to admit of being profitably navigated by barges, and therefore artificial channels require to be cut. Canals are extremely suitable in level countries, possessing rivers or brooks which can afford a due supply of water. In China, from a very early age, certain large rivers have formed natural canals longitudinally through the country from west to east, while artificial canals have been made to proceed in a cross direction from north to south, thus effecting a universal water communication throughout the empire. Canals existed in ancient Egypt in connexion with the Nile, on a similar plan to what now prevails in China. Notwithstanding that canals were known to have existed from a remote antiquity in the east, it was long before they were introduced into western Europe. In modern times, they were first used by the inhabitants of the Netherlands, in consequence of the extreme flatness of their country, and the numerous channels of water which intersect it in all directions, in connexion with the lower branches of the Rhine, and other rivers. In Holland and Belgium, therefore, canals in a great measure exist as an essential requisite in the general arrangements of the country, and are, in point of fact, so many wet ditches or drains to receive the superfluous waters.

In countries differently constituted, canals are constructed only with reference to the profit, in the form of commercial speculation. The great question, accordingly, in forming the project of a canal, is, whether the anticipated amount of traffic will raise tolls sufficient to compensate the outlay of the undertaking and subsequent charges for repair and superintendence. It simplifies such an inquiry to know the following truths in reference to cost of conveyance. The cheapest mode of conveyance is by sloops, smacks, brigs, packets, steamboats, &c., and these will at all times be employed for heavy and bulky goods, such as coal, barrels of liquids, iron, and other cumbrous materials proceeding coastwise. The next cheapest mode of conveyance is by barges on rivers; and the next is by means of canals. After this are ranked, in point of economy, conveyance by land, on railways and roads, the last being the dearest, though often the only means of transport which can be obtained. According to this view, canals can never answer as profitable speculations, when they have to compete with coasting vessels of any description, or with any species of conveyance by rivers. They cannot even in certain circumstances compete successfully with railways, on account of the slowness of speed at which barges or boats are drawn along them; and as speed is becoming daily a matter of greater moment in traffic, canals are gradually losing the conveyance of every kind of goods for which quickness of transit is desirable. For the sake of economy in national resources, it is very *desirable* that these truths in statistics should be *generally understood* and remembered.

When the undertaking appears warrantal careful consideration of circumstances, the to be taken into account is the obtaining of a supply of water, and the fixing on the best— most level and unexpensive—line of route. parts of England, where an enormous traffi reckoned upon, canals have been projected an on a stupendous scale; mountains have been to admit channels of water through them, val by embankments, and bridges built in the for ducts across rivers; in short, no expense spared to render the inland navigation comp

The supply of water necessary for a cana level throughout its course, is small in compa that of one pursuing an uneven line. When common level of surface, the only expenditu is by evaporation; but when the level is vario loss is incurred at the locks in raising or low sels. A lock is a portion of the canal enclos ing doors, and must at least measure the l vessel. If a vessel is to be raised from on another, it is drawn up to the doors of the these are opened to admit it. Having sailed lock, the doors are closed behind it, and it i kind of prison from which there is no appeal While in this situation, the doors at the oppo the lock, which retain the water at the hig are slowly opened, and admit a rush of the l which speedily buoys up the vessel, and al sail off along the higher level. The lock is diately emptied, but remains full of water, an fore ready to be employed in letting a ves When the vessel approaches, and is fairly i lock, the upper doors are shut, and then the lo are opened; by this means the vessel is carrie lower level along with the rush of liquid, and on its course. A lockful of water has now been shot from a higher to a lower level on t and is lost, unless required for lower locks. T inundation of the banks from the issuing of w the locks, waste outlets require to be provide tain distances, particularly at the lower term the line of canal. The provision of water to s locks is ordinarily from an artificial lake whic blished near the highest ground in the line.

The breadth of most canals varies from t thirty feet, and the depth from four to six feet depth of water be sufficient to keep the ves touching the bottom, no greater volume is n for less power is required to pull a boat upon than a deep water, there being less liquid ag displaced. At one side of the canal a narr called the towing-path, is constructed, and u the horses which drag the vessel proceed. T difference in the manner in which the draggin attached to the vessel. In Holland it is the pr attach the rope to near the bow of the boat cause it to proceed over the outer extremity or species of mast, so as to keep it considerab the water and prevent its friction on the bank is not attended to in England, where the rope direct from the bow to the horse, and, except w state of great tension, it trails along the bankand of the water. In either case, the draught of t is exerted with a loss of power, for instead of fair draught behind, it is oblique, or in the dir the rope slanting to the vessel. The tendenc draught is to bring the boat to the shore, counteracted by the helm, and this again assis minishing the general amount of available pow

Throughout the canals of England and S only one horse is employed to drag a boat, h the extent of from fifty to seventy tons; and t weight dragging after it in a manner most dis geous, it will travel at the rate of two miles an or three miles an hour. That one horse sh capable of drawing fifty tons of goods in this s sive manner, gives an apparently favourable canal conveyance; but laying all charges on

re; and I think that more water actually stands on a very convex road, than on one which is reasonably flat.'

In laying out a new road, it is of some importance that the rises and falls be not too great. The most approved angles of ascents and descents in England are about one inch in a foot—from this to one inch in a yard. In order to obtain ascents not exceeding these, it is necessary in our uneven country to wind up a hill instead of going directly over it. In such cases the road is to be built upon the side of a hill, and this is considered the most advantageous ground upon which a road can be built, provided the hill has not too great an ascent; because what is taken from the upper side serves to form the embankment on the lower side. While we are speaking of embankments, we may mention the English method of forming them, which is so manifestly superior to our own, that it deserves to be imitated. 'The natural sod, which would be covered by the base of the embankment, having been cut off and laid aside, the earth is then wheeled or carted on to form the two outsides, which are raised to the required height, leaving the middle open. The sods are then placed on one another, the grassy surface at right angles to the face of the outer slopes, forming as it were a battering wall of sods against the embankment.' This method is sound and effectual in preventing the banks from washing away and gullying. While the outsides are forming, the lumps of earth, stone, &c., run downward to the middle; and in this way the whole is finished. When the work settles, it is found to tend towards the centre, thus preventing the outside slopes from giving way."*

The following judicious observations are made by the same authority on the subject of fences, and junctions of different roads:—"Fences are necessary along the sides of a road in all enclosed countries; but they should never be allowed to rise higher than four feet on common roads. It is absolutely necessary that the air and sun have free admission to a road; besides, where the fences are high, it gives a sweeping power to the wind, which is not beneficial. Mr Telford thinks that fences should never be more than four feet high, and that all trees within twenty feet of the sides of the road should be removed. He also thinks that twenty per cent. of the expense of repairing or improving roads is incurred by the improper state of the fences and trees along the sides, particularly on the sunny side; this will be manifest to any person who will take the trouble to examine the condition of that part of a road which is much shaded, compared to the other parts which are exposed to the sun and air.

"The junction of one road with another requires a little attention: it should always be made at right angles, and on the same level, if possible. All engineers agree that plantations of trees should not be made close to roads; but what the distance should be, depends on the elevation of the country, the soil, the breadth of the road, as well as its direction, &c. &c. An elevated situation is always more exposed to winds than a level or hollow. A broad winding road has chances of the least influence of the sun and wind, according to the obliquity of its angles; a road running north and south, though planted closely on both sides, will enjoy the sun during a part of every day in the year; one running east and west, planted on the south side with trees forty feet high, or more, will enjoy no sun during the winter months. The least injurious trees are single rows trained to high stems, properly pruned."

For some time after a road has been laid with fresh materials, it presents a rough surface, unpleasant to the feelings of those who are conveyed over it; but this roughness is gradually abated, the small stones are crushed into a compact mass, and finally, the road is smooth, hard, and level. The length of time that may elapse before any new repair is required, depends on the amount and kind of traffic, as well as the weather. Rain is a great enemy to macadamised roads, and particularly so when accompanied with much traffic. The water lies on the surface, and softening the material, the action of the horses' feet and of the wheels causes a certain depth of thin liquid mud. This mud should, by all means, be scraped off to a side, for the longer it lies, the stratum beneath is the more liable to be cut up and damaged. The scraping of the roads, therefore, becomes an essential duty of all who are interested in preserving the highways economically in repair. When the mud which is scraped aside thickens by exposure, it should be carted off, and may be employed on many soils as a useful manure. Besides containing a proportion of refuse from horses, it is loaded with particles of iron from wheels and horse shoes; and being substantially silica or ground stone, it may be administered with special advantage to heavy clay grounds.

Roads exposed to much traffic require to be renewed in surface at least once a-year. The first indications of decay are observable in the form of slight hollows, and ruts next make their appearance. In some cases, where the decay is only partial, a small quantity of metal may be scattered in the hollows, bringing them up to a level with all around. However, this is not usually done on well-kept roads near large towns. There the road undergoes a thorough repair once a-year, which is preferable to partial mendings. The best time for repairing roads is about November, or before the winter frost and snow set in. In commencing the repair, the road should be picked across, at intervals of twelve or fifteen inches. This is done by men, each having a pick by which he indents the hard bottom, or forms scores an inch deep in the road. The use of such a preliminary process, is to cause a ready union between the new and old materials. If the fresh metal were scattered over the old road, without any preparation, it would with difficulty unite to the substratum, and at best form an upper crust, which would be too easily damaged.

With respect to the keeping of roads in efficient repair, the most advantageous plan consists in assigning the entire duty to a contractor. This person, by undertaking to keep all the roads in a county or district in constant and uniform repair, is able to execute his functions much more economically than the private gentlemen who act as trustees of the highways and turnpikes. The trustees appointed by local acts of parliament to superintend highways, now generally employ contractors to keep the roads in repair at a specified price per mile, the payment being made from funds collected from the lessees of the toll-bars.

The aggregate length of the turnpike roads of Great Britain is now calculated to be 25,000 miles, at a general breadth of from fifty to sixty feet.* The cost of keeping these roads in repair differs considerably in different counties. In the neighbourhood of London, the annual cost is about L.550 per mile, in Yorkshire it is L.60, and in Wales L.20. The average is about L.50. Nearly all the road trusts are in debt for borrowed money. It is supposed that the debt is on an average L.320 per mile, or probably L.6,000,000 for the whole.

Law of the Road.—For general convenience and safety, drivers of vehicles and riders, in travelling along a road, are expected to take a particular side; and this practice is now so well understood, and is in itself so proper, as to have become a part of the common law. The law of the road is, that when drivers meet from different directions, each shall keep his left hand to the wall or footpath. Secondly, when one driver overtakes another, and wishes to pass him, he must keep his left hand to the vehicle which he passes. In the case of either meeting or passing, each party is entitled to the half of the road. The same rules apply to riders. If these regulations be neglected, and an accident occur, the

* Turnpikes were so called from poles or bars, swung on a pivot, having been placed on them, and turned either way when dues were paid. Gates are now substituted for these poles in Great Britain. In Germany, the pole is still used, one end being depressed to raise the other, and so permit a free passage.

* Scientific Tracts. Boston: 1833.

some of the lines of canal, since the introduction of railways, has sunk in an extraordinary degree, greatly to the loss of the proprietors. Ireland has about 300 miles of canals, mostly government undertakings, and in general they possess little trade.

Scotland has a number of canals, but they are chiefly confined to the western and mid district of the country. That which possesses the largest traffic is the Forth and Clyde Canal, reaching from the Clyde, a short way above Dumbarton, to the Forth at Grangemouth. This canal, which was opened in 1790, and affords a ready communication for small vessels between the east and west coast, extends 39 miles in length; its highest level is 160 feet, with 20 locks on the eastern acclivity and 19 on the western. The canal is connected with Glasgow by a side cut; and it is now joined by the Union Canal, which extends from near its eastern extremity to Edinburgh. This latter canal has proved a poor commercial speculation, but has been of great service to Edinburgh, by introducing coal at a cheap rate to the city, and affording an exceedingly convenient means of conveyance for goods to and from Glasgow. The Caledonian Canal is formed in a great measure by a chain of lakes, stretching across the country from Inverness on the east to Loch Eil on the west coast, a distance of 59½ miles. The canal part is 20 feet deep, 50 feet wide at bottom, and 110 feet at top, which affords a passage to frigates of 32 guns, or merchant vessels of a similar size. This great canal was undertaken as a public work by government; and after a labour of eighteen years was opened in 1822, having then cost £800,000. It possesses 13 locks on the east and 12 locks on the west coast, the highest level being 94 feet. By this canal the dangers of rounding the northern extremity of the island, by the Pentland Firth, may be avoided; but from the prejudices of seamen it has never been much used, and is now abandoned by government to a private company. As a means of allowing steam-boats to run between the Clyde and Inverness, the canal has been of great public service.

CONVEYANCE BY STEAM POWER.

STEAM-BOATS.

Until the year 1807, the only means of communication by sea was by sailing vessels affected by the winds, and on the land by the power of draught in animals, both of which were exceedingly defective. In 1807, Fulton introduced the use of steam-propelled vessels on the Hudson, between New York and Albany. In 1812, Bell introduced a similar mode of steam navigation on the Clyde at Glasgow; and in two or three years afterwards, steam-boats were common on British rivers and on the sea around the coasts. We do not consider it of the least moment to mention how or by whom steam propulsion was first discovered; the merit of this and every other great invention is alone due to the person who brought it into practical use, and in the present instance it is clear that that person was Fulton.

Leaving all account of the *mechanique* of steam power, as applicable to propulsion, to be given in our article on the STEAM-ENGINE, we need here only allude to the extraordinary changes which have been effected *upon conveyance* by sea and land by this newly applied *motive force*.

Steam navigation has hitherto been chief to coasting and voyaging on rivers and estu in these respects it has greatly altered th of transit. In 1840 there were in the Uni dom and colonies 630 steam-vessels, possessi gregate burden of 71,000 tons. The rivers they principally plied were the Thames, the the Clyde, the Forth, the Tyne, and the Seve Clyde alone owned 76 steamers, having ma tons. Besides those which were devoted t trips up and down these rivers, a large propor regularly between different coasts in Britain land, and between different ports and the From the Thames, also, steamers proceeded different ports on the continent. In short, are now found traversing the whole line of co ing up and down rivers, and holding comm with ports in distant parts of the globe.

One of the finest lines of large steamers no ration in Britain is that between Edinburgh don; it has for several years consisted of fr eight vessels of about 300 tons each, and regularly twice a-week. Formerly, the pa sailing smacks occupied, on an average, six days, but sometimes it was three weeks; voyage by steam is performed with remark cision in from 48 to 54 hours, the distance miles. The lines of steam-packets between and Liverpool, Glasgow and Belfast, Liver Dublin, Bristol and Cork, Aberdeen and Lond dee and London, London and Rotterdam, Lon Hull, London and Newcastle, Southampton an Dover and Calais, are all upon a great scale, a an amount of communication for passengers sit for goods, of which no description of ours c vey any just idea.

The above may, however, be considered as clude those vessels which proceed on voyage more than two days' duration. Latterly there h added steamers which proceed between Engl Lisbon, and thence to Maderia; also steamers to the Cape of Good Hope; and more lately still, s which make the voyage across the Atlantic, an means of regular communication between Bri North America. The Great Western, a ste 1340 tons burden, was the first large vessel whi regularly on this station. This vessel depart Bristol on the 7th of April 1838, and reach York on the 23d of the same month; but the cl occupied on the passage were only 14. This established the practicability of steam-vessels the Atlantic, and now there are several whic regular intervals. Besides crossing from Londo tol, and Liverpool, to New York, and returnin is also a line of large steamers which sail Liverpool and Halifax in Nova Scotia. The la the Atlantic steam-boats is the British Queen measures in entire length 275 feet. Her two are of 250 horse power each, and she is calcu carry 1862 tons. The outward voyage of th this magnificent steam-vessel requires a cons of 540 tons of coal, and her homeward voyag days 360 tons. Larger and more powerful ves now in preparation.

On the coasts and rivers of North America navigation has been carried on to a much gre tent than in Great Britain or any other coun 1834, there were 234 steam-vessels on the Mi sissippi, and other western waters; but now th ber is above 500. Some of the American steam are larger than any in Britain, and also more in decoration; but they are much more liable dents, from the employment of steam at a v pressure, and a general carelessness in the management.

The Rhine, the Seine, the Danube, and oth rivers on the continent of Europe, are now n by steam-vessels, chiefly for conveying passeng engines used are mostly made in England.

lway, or *chemin de fer* (road of iron), as it is
y our French neighbours. By the establish-
railways, a way was opened for the adaptation
power to locomotion, and now, as is well known,
come generally into use.
arliest railway of which there is any account,
constructed near Newcastle-upon-Tyne. In
North's Life of Lord Keeper North, he says
his place, in 1676, the coals were conveyed from
m to the banks of the river, "by laying rails of
exactly straight and parallel; and hulky carts
ade with four rullers fitting those rails, whereby
riage was made so easy, that one horse could
ur or five chaldrons of coal." One hundred
erwards, about 1776, Mr Curr constructed an
lroad at the Sheffield colliery. The rails were
ed by wooden sleepers, to which they were
In 1797, Mr Barns adopted stone supports in
ad leading from the Lawson main colliery to the
ear Newcastle; and in 1800, Mr Outram made
hem in a railroad at Little Eaton in Derbyshire.
-five years afterwards, this species of road was
ully adopted on a public thoroughfare for the
ransation of merchandise and passengers, namely,
kton and Darlington railway, which was open-
n 1825, and was the first on which this experi-
as made with success. From that time, accord-
new era commenced in the history of inland
nce.
s remarkable circumstance, that the early prac-
railway conveyance could not imagine that a
, moved by steam power, could proceed along
without the aid of toothed wheels and a rack;
vercome this imaginary difficulty, no small de-
expense and labour was fruitlessly incurred.
the year 1815, Mr Blackett, of Wylam, near
tle, effectually proved, by repeated experiments,
adhesive power of the wheels on the rails was
mes sufficient to cause a progressive motion in
ne, with a train of loaded carriages, upon a rail-
her level or with a small acclivity. Important
this discovery, fifteen years elapsed before steam
ives were established. This great triumph of
urred in connexion with the opening of the
ol and Manchester railway, on the 15th of Sep-
1830, since which period railways have spread
opulous parts of the country.
le as is the idea of a railway, a prodigious ex-
s necessarily incurred in bringing it into prac-
eration. All inequalities of surface in the ground
e removed, low parts must be filled up by em-
nts, high parts must be reduced, eminences,
t would be impolitic to level, must be perforated
nels—the whole route being brought as nearly as
s to a level. Besides, the land over which it is
ed must be purchased, frequently at an exorbi-
st; and the preliminary expense of overcoming
pposition and procuring an act of parliament to
h the line, sometimes amounts to as much as
per mile. An entire charge of £30,000 per mile
dered a moderate outlay in the construction of
s in Britain.
ng line of railway that has yet been formed is
ly level throughout, but the acclivity is seldom
han one foot per mile, and this does not produce
tardation, which it would be absolutely neces-
obviate by an excess of expenditure. Every
so, is curved, or bent from a truly straight
n, at various places in its course; and this is
evil which it is necessary to tolerate to a cer-
tent rather than avoid by uneconomical outlay.
e reasons now stated, nearly all railways are
perfectly straight nor perfectly level; and so far
is the case, there is a loss of power in drawing
s along them. Yet, in the most disadvantageous
circumstances, the railways are so comparatively
and suitable for transit, that they allow the
approach to a total absence of friction. It is
ng of notice, that the absence of friction in rail-

ordinary roughness of the iron.

Rails.—The experience of ten years has introduced a few improvements in the construction and management of lines of railroad. At first, malleable iron rails were supposed to be preferable to those of cast-metal; but now it is understood that cast rails, if properly made, will endure all the tear and wear to which they can be fairly subjected. To be of the strongest and best form, each individual rail should be at least twelve feet in length, six inches in depth at the two ends, and thence gradually deepening beneath in the fish-belly form to the centre. The thickness should be fully one inch, and the upper surface, on which the wheel is to run, should be an inch and three-quarters or two inches, so as to project laterally like the cross top of the letter T. The rails are to be supported at their joint extremities, where they are pinned together, and also at intervals of every three feet. The supporters should consist of transverse bars of wood, sunk in the ground; by being thus crossing from the one track to the other, both lines of rail are kept from separating or shifting, and if there is any tendency to subside, both are equally lowered. On many lines of railroad stone sleepers are preferred to wood, but, as it seems, with no adequate advantage. Stone sleepers present too unyielding a base to the rolling of the wheels, and cause a jolting most injurious to the mechanism of the carriages. In several instances, lines with stone sleepers have been taken up, and wood substituted. The railways in Belgium are laid on wood. To attain the highest perfection in the mode of laying rails, a plan has been followed on the Newcastle and Shields line, and also on that of the Great Western between London and Bristol, of placing rails having an even under side upon longitudinal beams of timber, which are united at certain intervals by transverse bars: thus the whole substructure is a handsome framework laid on the ground, and presents the best species of support. In general, this will be found too expensive a kind of railway; and it may be anticipated that the method of fixing rails upon cross bars of wood, at intervals of three feet, will ultimately come into universal use.

are about an inch and a half in depth. T

Inclined Planes.—Where the inclinatio
is greater than that for which the ordi
calculated, the ascent must be effected by
additional power, the amount of which
computed, since in those parts no addi
of the cars or wheels is to be provided
the additional resistance arising from gr
overcome. If, for instance, the addition

train, the locomotive consists of a long iron
ar cylinder supported by six wheels, with a
y rising in front, and affording standing space

ising 1 in 96, and extending 1¼ mile, the engine
sisted by another engine called the Samson,
e ascent was performed in 9 minutes. At start-
n fire-place was well filled with coke, and the
upplied to the tender accurately weighed. On
g at Manchester, the fire-place was again filled,
e coke remaining in the tender weighed. The
nption was found to amount to 929 pounds net
being at the rate of one-third of a pound per
mile. Speed on the level was 18 miles an hour;
ll of 4 feet in a mile, 21½ miles an hour; fall of
in a mile, 25½ miles an hour; on the rise over
es, 8 feet in a mile, 17½ miles an hour; on level
sheltered from the wind, 20 miles an hour. The
as moderate, but direct ahead. The working
slipped three times on Chatmoss, and the train
arded from two to three minutes. The engine,
occasion, was not examined before or after the
y, but was presumed to be in good working order.
he 29th of May, the engine called the Samson
ing 10 tons 2 cwt., with 14-inch cylinders, and
stroke; wheels 4 feet 6 inches diameter, both
being worked by the engine; steam 50 lbs. pres-
30 tubes) was attached to 50 waggons laden with
ndise; net weight about 150 tons; gross weight,
ng waggons, 223 tons 6 cwt. The tender weighed
making a gross load (including the engine) of
ns 3 cwt. The engine with this load travelled
Liverpool to Manchester (30 miles) in 2 hours
minutes, exclusive of delays upon the road for
g, &c.; being at the rate of nearly 12 miles an

road. Upon a level, it was 12 miles an hour;
descent of 6 feet in a mile, it was 16 miles an
upon a rise of 8 feet in a mile, it was about 9
n hour. The weather was calm, the rails very
ut the wheels did not slip, even in the slowest
except at starting, the rails being at that place
nd greasy with the slime and dirt to which they
ays exposed at the stations. The coke consumed
journey, exclusive of what was raised in getting
steam, was 1762 lbs., being at the rate of a
of a pound per ton per mile."

ral Appearance and Management.—In America
lgium, most lines consist of but one track; in
Britain all possess two tracks, suitable for trains
n opposite directions, besides which there are
s at which quick-going trains may pass those of
motion. At certain convenient points along the
re are stations or houses, at which the trains stop to
and set down passengers, and there is no stop-
any other place. On most of the lines there
w trains, taking goods and second-class, or an
kind of carriages, and fast trains, taking only
l second class carriages; some lines also have
ins, which proceed at more than usual speed, and
only first-class carriages, stop at fewer places by
. The first-class carriages are covered, and
e three coach bodies united, but of more com-
s dimensions; second-class carriages are open
ides, and not lined with any stuffing; a third-class
s are entirely open; goods carriages are open
on which the articles are piled and fastened;
for cattle are open, with a railing round the
All the carriages in a train are linked one to
by strong iron hooks, and to prevent them
ocks against each other, the various carriages
vided with projecting rods on springs, cushioned
outer extremities. Generally, the fares charged

for transmission are higher than they need be; a common charge is at the rate of 3d. per mile for each passenger in a first-class carriage; and it is understood that lower rates would create more than a compensatory amount of traffic.

There are certain excellences in the arrangements of all the railways which deserve to be mentioned. Each line, being the property of a private association, is secluded from one end to the other from the intrusion of the public; and therefore no jostling or confusion takes place, either upon entering or leaving the carriages. The rails of one line, likewise, join those of another, by which means carriages generally proceed onwards without changing passengers or luggage. A carriage in which passengers take their seats at London goes straight on to Preston—that is, along the lines of three companies. The extraordinary magnitude of the railway undertakings has enabled the directors to organise rules which could never be enforced in the irregular scramble of stage-coaching. It is customary to dress the subordinate functionaries on all the lines in a uniform resembling that of the London police—each man having his number inscribed in figures on some part of his dress; so that, if any one be guilty of incivility or inattention, he can be easily reported to his superiors. There is one pleasing peculiarity in the arrangements, which is entitled to the highest commendation: it is the rule that no officer shall on any account take a fee from passengers, on pain of instant dismissal. Those who imagine that fees to guards, coachmen, or waiters, are requisite to ensure civility, will be surprised to find that railway attendants are infinitely more polite and attentive than their brethren of the coach conveyances. This, in itself, gives travelling by railway a great superiority over all other modes of public conveyance.

The London and Birmingham line, which was the first completed after that of Manchester and Liverpool, has always appeared to us to be among the best managed of the various railways, as well as the most complete in all its arrangements. There are accommodations on this line which are to be seen on no other. On all the lines there are waiting-rooms both for ladies and gentlemen at the different stations; but exclusively of those on this line, there is a large and commodious house of entertainment at the Birmingham terminus, where meals stand ready prepared for the passengers. At Hampton, a place half way from the metropolis, and where the train stops ten minutes, there is likewise a large establishment in the form of an open booth or shop, where tea, coffee, or viands of a more substantial kind, with different liquors, are sold on the instant to those who require refreshment.

Passengers who make the journey for the first time by the mail train, will be amused by observing a travelling post-office in the string of carriages. This "Grand Northern Railway Post-Office," as the inscription on its side denotes, is a carriage consisting of two small apartments, one of which is appropriated to the guard, whose duty is to exchange the bags, and the other is fitted up with a table for sorting letters, and holes round the walls for their reception. The manner in which the duties of the clerk and guard are performed in this flying post-office, is strikingly significant of the new order of things introduced by the railway system. Outside the vehicle a species of net is extended by a hoop, and into this the letter-bags are dropped as the train sweeps onward in its course, the bags which are to be left being at the same time tossed from the window by the guard. The fresh bag of letters being received, it is speedily opened, its contents re-arranged, and a new bag for next town being made up, it is projected as before at the place of its destination. By this means a letter may be written, sent through the post-office, and delivered at the distance of twenty miles, in the space of a single hour.

The number of railway companies incorporated by act of parliament up till January 1839, in Great Britain and Ireland, was 107, and the capital which they were allowed to raise by shares was £41,610 were besides allowed to raise by loan £16,1 considerable number of these railways bei or at least crude speculations, have never c and the number of railways actually begun pared or finished at the beginning of 1840, i kingdom, was only about fifty. The princip —the Liverpool and Manchester Railway, a two miles long, and uniting these populous

London and Birmingham Railway, about e and twelve miles long, connecting the metr the centre of England; the Grand Junctio continuing the London and Birmingham lin Liverpool and Manchester, and also to a r ceeding northward to Lancaster, and thes most important thoroughfare obliquely acros try; the Midland Counties, North Midland, North of England railways, connecting the of trade in Northumberland, Durham, Yor Derbyshire, with the London and Birmin the Newcastle and Carlisle Railway, connec towns; the Great Western Railway, about dred and seventeen miles long, connecting L Bristol, and with smaller tributary lines o the west of England; the South-Western about seventy-seven miles long, connectin with Southampton; the Manchester and L way, connecting these populous towns. In the Edinburgh and Glasgow Railway, and th and Ayr Railway, are the principal lines. Th of the whole of these undertakings is the Gra ern. This line has two tracks, each of seven while on all other railways in this country th between four and five feet; the carriages, which run on the Grand Western, must be n confined to itself. The most prosperous of al is that of the London and Birmingham, th revenue of which is upwards of £16,000: t revenue of the Grand Junction, which joins it,

The speed at which railway trains usually from twenty to twenty-five miles per hou sometimes it is much more. At the ordina speed, a journey from London to Liverpool by train is performed in about nine hours; and w ways are extended north to Edinburgh, the from London to that city will be performed in hours, or perhaps less. Travelling by railw of the common rates of speed is attended personal danger than stage-coaching, because motives are perfectly under control. Any personal injuries which have occurred on rail with scarcely an exception, attributable to the ness of the engine-drivers, and by the employ superior class of men to direct the motions of t this fruitful cause of mischief is in the course obviated. With this improvement, conveyanc ways will be ranked among the most useful pendous inventions of art.

ience teaches that the offspring of any kind
l is similar to its parents, though slight varia-

necessary to take great care to avoid errors arising from variations in the forms of animals at different periods of their existence.

A number of species, differing from each other in trivial points, but having a strong general resemblance, are said to belong to one *genus*. The genera most nearly allied are united into one *family*; several families into an *order*; and several orders into a *class*. The class, therefore, contains a very large number of species, many of them differing widely from each other, but all agreeing in some prominent and important character. And the classes composing the Animal Kingdom are arranged under four groups, on account of their correspondence in certain general particulars, and their difference in others: these are called *sub-kingdoms*. This is the alphabet of the science; and when this has been acquired, the student will proceed to his grammar, which consists of such a knowledge of the principal divisions of the animal kingdom, as will enable him to read the language of nature with understanding, so as to learn from the simple *name* much respecting the structure and character of the particular specimen, of which he would otherwise be ignorant.

PRIMARY DIVISIONS OF THE ANIMAL KINGDOM.

In considering the primary subdivisions of the Animal Kingdom, it is desirable to view them at first in their most simple aspect, and to regard merely the points of agreement amongst all the beings contained in each group, and their most striking differences from the members of other groups. The subordinate differences amongst the forms contained in any one of the primary groups, will be subsequently attended to. Following the arrangement of Cuvier, which in this respect is unexceptionable, we divide the animal kingdom into four sub-kingdoms—VERTEBRATA, ARTICULATA, MOLLUSCA, and RADIATA. The principal characteristics of these will now be pointed out.

The VERTEBRATA derive their name from the peculiarity of their skeleton, which essentially consists of a back-bone or spinal column, formed of a number of separate pieces, so united as to combine great strength with flexibility. These are termed *vertebræ*. Each is perforated with a large aperture; and, when all are united, a continuous tube is formed, in which is lodged the *spinal marrow*, a very important part of the nervous system (which is quite different from the *marrow* of other bones, which is an oily substance, subservient to nutrition). At one extremity, the spinal column is extended into a large bony structure, the *skull*, which is especially designed for the protection of the cerebral or nervous mass, which may be regarded as the principal part of the spinal marrow) and of the organs of sense connected with it. At the other extremity it is continued into a *tail*, the size and prolongation of which are usually greater in proportion to the small size of the body. Connected with this spinal column are a series of *ribs*, which pass off from it on each side, and generally meet again in a breast-bone, enclosing a cavity (that of the chest), in which are contained some of the organs of nutrition. Appended to it are two pairs of *limbs* or *extremities*, which are usually the [illegible] They have all *red* blood, which is propelled the system by a muscular heart. The mou nished with two jaws, which are placed one *before* the other; there are never more than they never open sideways as in the Articula are usually armed with teeth, which are in very analogous to bone.

The Vetebrata are characterised by a high of *intelligence* than is possessed by any oth The animal powers of sensibility and spontan tion are also greatly developed; and in ac with these, a complete symmetry or corres between the two sides of the body is observa nally. But this symmetry does not exten organs of vegetative life, which are irregu posed in the cavities which they occupy.

In the ARTICULATA, the skeleton is *external*, ing not only the nervous system but the ent with the muscles which move it; these, as is in the crab or lobster (which are the larges of this group), being attached to the interi firm casing. This skeleton is formed of a n pieces or *segments*, jointed or *articulated* t whence the name of the group. The centi very characteristic illustration of this structu legs, as well as the body, are here seen to be in a firm envelope, of which the pieces are c together by a flexible membrane; and the se the body are nearly alike along its entire leng in the higher classes of this sub-kingdom, w movement is performed entirely by the legs, a tacea, or by the legs and wings, as in Insects ments of the body to which these are attached united together, in order to give their muscl point from which to act. But, in the lower cla as the leech and worm, where the extreme of the body, and the change of its dimension only means of locomotion (no members being the whole envelope of the body is so soft, that sion into segments is scarcely perceptible. Th system of the Articulata is not by any means developed as that of the Vertebrata; in ge organs of taste and vision are all that can be in them; those of hearing and smell being only by a few of the higher tribes. The numbe which these are present, is often very great; never less than six. More than one pair of jaw exist, and they open laterally. The blood is w only in the highest classes is propelled by a heart. The Articulata have their whole adapted to great activity of locomotion, and t formance of *instinctive* actions of a high c The class in which this is most evident—that is by far the largest in the whole animal The body, which is usually of small size, di principal bulk from the organs of *animal* life, the muscles which move the extremities; and *ral symmetry* is even more remarkable in the V the Vertebrata, extending in part to the organ trition as well as to those of sense and motion.

The group of Mollusca must be described its negative than its positive characters. The the name imports, is here soft, and destitute of

keleton. It is enveloped in a loose elastic skin, is termed the *mantle;* and the outer surface of as often the power of secreting a shell. But this s by no means adapted to the form of the animal; no regular series of joints for the purpose of faci- g the movement of the body, and it has no pro- ions for giving protection and support to locomo- ppendages. Moreover, of two species closely in general structure, it is often present in one sent in the other, as in the snail and slug; and, present in both, often differs much in form; so t cannot be regarded as a part of the structure ial to our idea of a molluscous animal. That s principally founded upon the softness of the the high development of the organs of digestion, ion, &c.—in fact, of the system of *vegetative* life, constitutes the bulk of the body; and, on the ıry, the low development of the powers of sensa- ınd locomotion, and the organs of *animal* life. of them are entirely fixed to one spot during all ıe very earliest period of life; and in the lowest s, there is a tendency to aggregation into a com- structure, like that which is seen in the zoophytes. umber of Mollusca possessing *active* powers of lo- ion is comparatively small; and of those which t entirely fixed, the general character is *sluggish*. The blood is generally white; and is often pro- by a powerful heart, and distributed through a ex system of vessels, even where the animal seems ; inert. Where any correspondence between the les of the body exists, it is usually restricted to parts which are concerned in the functions of l life; especially the head, on which the organs ·ial sense (when they exist) are placed.

division RADIATA includes the lowest members of imal kingdom, and those, therefore, which most approximate to vegetables. There is a great ıcy in the animals of this group to associate into und structures, in which each individual has a ı degree of connexion with the rest. Thus are l those assemblages which, from their general blance to plants, are commonly called *Zoophytes* il plants). But as, in investigating the charac- a tree, we study the separate flowers and leaves, tudying the zoophytes, we consider the individual s which form them. These polypes, in common he higher kinds of radiated animals, which are l to exist separately (such as the star-fish), are uished by the *circular* arrangement of their or- ıround a centre, in which the mouth is placed; om this arrangement the name of the group is d. There is thus a repetition of similar parts; s in most other instances where this is the case, it power of reproducing those which have been In many of the Radiata there is no distinct skele- ı others a very firm support exists, almost always ·ing of the circular arrangement of the soft parts. ea-anemone is a good example of the lower forms group; the star-fish or sea-urchin of the higher; ew species belonging to it possess much sensibi- power of locomotion. In many instances there o distinct blood-vessels, but the nourishment is ved to the tissues by direct absorption from the ial surface and from the walls of the stomach.

SUB-KINGDOM—VERTEBRATA.

ting off with the idea of a *vertebrated* animal as ossessing an internal bony skeleton, essentially sed of a jointed spinal column, containing the marrow, and expanded at one extremity into a ase for the reception of the brain, having usually ers or appendages for locomotion, which never d *four* in number, endowed with all the five senses, a general with considerable activity, having red , and altogether a more complex organisation than ver classes possess, as well as a higher degree of gence—we next proceed to consider upon what principles this extensive group may be subdivided into others, which, agreeing in all these particulars, shall yet differ in other important characteristics.

The ordinary observer would readily establish three subdivisions or classes, upon the three well-marked types of form which he perceives to be adapted to existence in the three different elements. He sees that one large group is entirely confined to the water; that the form of its body is peculiarly adapted for motion in that medium; that its members are constructed for most advantageous propulsion in it; and that it is incapable of existing, at least for any length of time, out of it. This group he calls by the name of FISHES; and he naturally associates with it some of a higher class, which resemble it in external appearance and mode of life. Another large group he observes to be formed to pass a great part of its life buoyed up only by the air; that the form of its body, the construction of its members, and the peculiar covering with which these are invested, specially adapt it for this peculiar mode of support, and for rapid motion through the element it inhabits; and that it is incapable of existing for more than a few minutes under water. This is the class of BIRDS; and with it, also, the ordinary observer associates a portion of a superior class, which is adapted in part to a similar mode of existence. A third group would consist of animals possessed of four legs, adapting them to a residence on the earth, and to motion on its surface; these would also be found to agree in their incapability of living beneath water like fishes, or of rising into the air like birds. But further examination of these *quadrupeds* would disclose some important differences in structure and vital actions, which separate them into two great divisions, very widely apart from each other. It is soon observed that some are *warm-blooded*, maintaining a constant and elevated temperature, whilst the others are *cold-blooded*, their bodily heat varying with that of the atmosphere, and in general being but little above it; that the former are covered with hair or something analogous to it, whilst the latter are coated with scales; and that the former produce their young alive, or are *viviparous*, and nourish them afterwards by suckling, whilst the latter rear them from eggs, or are *oviparous*. Hence this group is subdivided by the naturalist into two, of which one—that of MAMMALIA—is superior in its general organisation to birds, whilst the other—that of REPTILES—is intermediate between birds and fishes. The scientific characters of these groups will next be considered.

FISHES are oviparous vertebrata, inhabiting the water, and respiring that element by means of *branchiæ* or gills, which are filamentous prolongations of the surface, into which the blood is propelled, in order to be brought into relation with the air contained in the surrounding water. The heart only contains two cavities; one of these receives the blood which returns from the system, and the other propels it through the gills, from which it is conveyed by the blood-vessels to the body at large. They are in general cold-blooded, but few of them maintaining a temperature above that of the surrounding medium. Living habitually in an element which is nearly of the same specific gravity with their bodies, fishes have no weight to support, and have only to propel themselves through the water. Accordingly, we find their structure adapted for great freedom of motion, rather than for firmness and solidity; progressive motion is chiefly accomplished by the lateral action of the spine, which is endowed with great flexibility. The vertebræ, instead of being articulated by a flat surface, as in the Mammalia, or by a ball-and-socket joint, as in serpents, have each of their surfaces concave, and these glide over a bag of fluid, which is interposed between each pair of vertebræ. The tail is flattened vertically; and it is by its movement from side to side that the fish is urged forwards, as a boat by a sculler. The *pectoral* fins, which answer to the hands of man, and the *ventral* fins, which represent the feet, serve rather as *steering* than as *propelling* organs; and they also assist in raising and depressing the animal

in the water. In a large proportion of this class, the skeleton is cartilaginous only; and in a few of the lowest the vertebral column is not divided into distinct portions, but forms one continuous tube of gristle or even of membrane only. The surface of the body of fishes is almost always covered with scales; and these are sometimes quite bony, and fitted closely together, especially where the internal skeleton is soft.

Reptiles are also oviparous, cold-blooded vertebrata; but, in their adult state, they breathe air, which is introduced into *lungs* or internal cavities; and they mostly are formed to live on land—those which inhabit the water being obliged to breathe at the surface. Their heart possesses three cavities, one of which receives the blood from the lungs and another from the system at large; the pure and impure blood are mixed in the third cavity, and the fluid is propelled by it partly to the lungs and partly to the body. Thus only part of the blood expelled from the heart is exposed to the influence of the air at each contraction; and this deficiency is accompanied by a general inertness of the other functions. Their motions are chiefly confined to crawling and swimming; for though a few at times can run and leap very quickly, their general habits are sluggish, their sensations obtuse, and their digestion slow. Hence they can exist for a long time with a very feeble exercise of these functions, under circumstances that would be fatal to animals in which they are performed with greater activity. In cold and temperate climates they pass the whole winter in a state of torpidity. There is greater diversity of form and structure among the members of this class, than in any other division of the vertebrated series. The *tortoises*, *lizards*, and *serpents* appear so different, that a common observer would separate them widely; and yet they not only agree in all the foregoing characters, but pass into each other by links of transition so gradual, that it is difficult to classify them. There is one group which, in its adult condition, bears a general correspondence with reptiles, and has been commonly associated with them; but which only arrives at this condition by passing through a kind of metamorphosis, like that of insects: this is the *frog* tribe, which includes several animals bearing the form of lizards and serpents, but differing from them in having a soft naked skin, instead of a scaly one, and in passing the early part of their lives—that which, in the frog, is called the *tadpole* state—in a condition like that of fishes in all essential particulars. These differences have been regarded by some naturalists as establishing their title to rank as a distinct class, to which the term Amphibia has been given.

Birds are, like fishes and reptiles, oviparous vertebrata, and like the true reptiles, they breathe air during the whole of their existence; but they are warm-blooded, having a heart with four cavities and a complete double circulation, by which all the blood returned from the system is transmitted to the lungs, before being distributed to it again. This high amount of oxygenation of the blood is accompanied by great activity and energy of all the organic functions, acuteness of the senses, and rapid and powerful locomotion. The class is further distinguished by the position of the body upon two legs only, and by the modification of the anterior members for wings; by the covering of the body with feathers, or something analogous to them; by the deficiency of teeth, in place of which the jaws are furnished with a horny covering or bill; and by various other characters of less importance. There is a peculiar conformity in the general structure and aspect of all the members of this class, with which scarcely any other animals are liable to be confounded. Birds have been not inappropriately termed the insects of the vertebrated classes.

The Mammalia agree with birds in possessing a complete double circulation and warm blood; and with reptiles *in breathing air*, and generally living on the surface *of the earth*; but they differ from all other vertebrata, *not so much in producing* their young alive (which is *the case in a few species* of reptiles and fishes), as in *their subsequent nourishment* of them by suckling—

from which circumstance the name is deriv
class is placed at the head of the animal king
only as being the one to which man belongs,
because it is that which enjoys the most
faculties, the most delicate sensations, the mo
powers of motion; and in which all the differ
ties seem combined to produce a more perfe
of intelligence; the one most fertile in resour
susceptible of perfection, and least the slave o
Although principally adapted to motion on th
we find one tribe possessed of the power of
the air like birds, and another formed to li
water like fishes; but both these agree with ot
malia in all essential characters, and differ re
from the classes with which their habits seem
ciate them. To the Mammalia is confined t
tion of the body by hair or fur; the nearest
to it being in the hair-like feathers of a fe
of birds. But the presence of this covering
means universal in the Mammalia.

CLASS I.—MAMMALIA.

The Mammalia are universally regarded as
ing the highest group in the animal kingdom;
from being the one to which man belongs (s
least, as his bodily structure is concerned), bu
possessing the most complex organisation, ad
perform the greatest number and variety of act
to execute these with the greatest intelligenc
contrast is here extremely strong between the
ing and the *instinctive* powers. When we com
sagacity of a dog, and the great variety of circu
in which he will display an intelligent adap
means to ends, with the limited operations o
sect, over which the judgment and will seem
no control, we cannot help being struck with th
ence. The one is *educable* in the highest deg
to man; the other could not be made to c
habits by the most prolonged course of discip
ascending the animal scale, we observe the
gradually becoming subordinated to the r
powers; and this may be particularly noticed
the members of the class under consideration
exhibit much variety in this respect.

If we regard intelligence as the chief chara
of the Mammalia, we should perhaps rest
principal varieties in the degree in which this
sessed by the several subordinate groups, as the
work of our division of the class into orders.
the sake of convenience the naturalist seeks fo
characters, and more particularly aims to esta
classification upon such as are external and ea
cognised. Such a classification will be *natural*,
will most nearly associate together the anim
have the greatest general resemblance, and w
widely separate those which have the least, in
tion as the characters which are selected for t
pose may be regarded as indicating the general
mation of the several animals. In this resp
structure of the extremities, and the arrange
the teeth, are found to be the most valuable.

From the general structure of the extrem
may learn much of the habits of the animal,
adaptation of its whole organisation to a pa
mode of life. These, for example, would be
determined by an inspection of the wing of a ba
flapper of a whale. Hence we shall not be far
we throw into distinct groups all the Mammalia
ing one or other of these modes of conformation
among those which are adapted to walk upon l
must seek for some slighter differences; and
may in the first place look for in the organs o
since on these will depend much of the addres
animal, and a number of differences connected
amount of its intelligence. The degree of perf
the organs of touch is estimated by the mo
mobility of the fingers, and the greater or les

RATA.

ease, aided by the lateral motion of the jaws, getable substances are reduced to a pulp. Ani- unguiculated fingers are susceptible of more their food is of different kinds; but it may at known from the form of the grinders, and from e of mobility and delicacy of the fingers. In grinders are formed, like those of the hoofed to triturate vegetable substances by elevated nd in these the extremity has the least power movement, the habits of the animals assimil- those of the Ungulata. In others, the grinders narrow, and are formed with sharp points and tting like the teeth of a saw; these are adapted ing animal flesh; and the jaws are fitted to- ke the blades of a pair of scissors, having no it a vertical one. In others, again, the sum- he grinders are raised, not into cutting edges, onical points; and they are thus adapted for down the hard envelopes of insects, upon ch animals prey. Finally, in mammalia which ted to a variety of food, but which employ e soft and pulpy than the tough and stringy lants, the summits of the grinders (which are ntirely with enamel) are raised into flattened tubercles, adapted rather for crushing and than for grinding or cutting. This is the case nd most of the monkey tribe. Thus, by the he grinders, the nature of the food may be at wn.

nt of the grinders or *molar* teeth, we find, in ibes that subsist entirely or in part on animal in some of the vegetable-feeders also, a single rojecting tooth on each side, which is termed rom its large size and prominence in the dog. y large in all the truly carnivorous animals, ables them to lay a firm hold of their prey. It ge, however, in some animals which are chiefly ous, as the boar; and in these it seems chiefly as an organ of offence and defence. Between es, and occupying the front of the jaws, are the or cutting teeth, the purpose of which is nearly in all animals which possess them, namely, to e food that is to be introduced into the mouth. ey are altogether absent, the food is obtained ngue. In the truly Viviparous Mammalia there r more than six incisors in each jaw.

variations in the form and arrangement of the ken in conjunction with the differences in the of the extremities, enable us to subdivide the *us* Mammalia into ten orders. In the first ey may be separated into the *Unguiculated*, g eight orders, and the *Ungulated*, containing . Of the former group, some have all three teeth, whilst others are deficient in one or hem.

unguiculated animals having three sorts of y be divided into the six following orders:—

ANA.—This contains man only, who is charac- eologically by the adaptation of his frame to posture, supported upon his posterior extre- ly, and by possessing *hands* (that is, feet osable thumbs) on the superior extremities

DRIMANA.—This order includes the apes, mon- , which have hands on all four extremities.

ROPTERA.—In this order, known as the bat anterior extremities are formed into wing- s, which enable the animals to rise into the irds.

CTIVORA.—The animals of this tribe, which the hedgehog, mole, &c., have the peculiar n of their teeth to insect food, just now de-

NIVORA.—In this very extensive group, of cat tribe may be taken as an illustration, the nifest, in the most remarkable manner, the n to devour animal flesh.

ACEA.—This order, properly restricted to those s of the whale tribe which feed on animal sub

stances, follows very naturally on the aquatic forms of the Carnivora; since its digestive system exhibits the same general character, although the adaptation of the extremities for swimming prevents them from showing the same form.

The two other orders of Unguiculated Mammalia are adapted partly to vegetable, and partly to animal food. They are—

7. Rodentia.—In these the toes differ but little from those of the Carnivora; but the jaws are deficient in true incisors, their place being supplied by the canines, which are brought very much forward (so that a wide interval exists between them and the molars), and are adapted to gnawing. This order includes the beaver, rat, hare, &c.

8. Edentata.—This order is so named from the absence of front teeth, sometimes also of canines, and even of molars. The extremities of their toes are nearly included in large nails, which approach in character to hoofs. To this order belong the sloth, ant-eater, armadillo, &c.

B. The *Ungulated* Mammalia form two orders only—those which *ruminate* (or chew the cud), and those which do not. The latter differ much amongst each other, but are associated into one order:—

9. Pachydermata.—In some of these the toes are still partly separated, in others they are entirely united. The food is mostly vegetable; all three kinds of teeth are sometimes present; in some the canines, and in others the incisors, are deficient. Besides the elephant, horse, hog, &c., this order properly includes certain aquatic forms, which have been commonly associated with the Cetacea, but which are strictly herbivorous, and approach very nearly to the hippopotamus.

10. Ruminantia.—This order, containing the ox, sheep, deer, &c., is a very distinct one, and is characterised by its cloven feet, the absence of incisors in the upper jaw, and the complex arrangement of the stomach, by which rumination is effected.

11. The sub-class *Ovo-vivipara*, is easily divided into two orders—the one having a pouch, or *marsupium*, in which the young are received and nourished for some time after their birth, and the other being destitute of it.

11. Marsupiata.—The animals of this order, which includes the opossum, kangaroo, &c., differ considerably amongst each other in their food and habits; and the arrangement of their teeth, or their *dentition*, varies accordingly. They have mostly three kinds of teeth, the incisors more than six in number, and their feet are unguiculated, with an opposable thumb, in some instances, on the hind foot.

12. Monotremata.—This is unquestionably the group which approaches most nearly to oviparous animals. It contains only two genera, in one of which the teeth are altogether absent; and in the other nearly so, the jaws being covered with a horny bill. In addition to five claws on each foot, the males have a peculiar spur on the hind ones, like that of a cock.

The foregoing arrangement, founded entirely on external characters, does not give an altogether accurate representation of the relative intelligence of the different orders. If this be taken as the guide, we should first arrange the Viviparous Mammalia into a *Zoophagous* (or animal feeding) and a *Phytophagous* (or vegetable-feeding) series, of which the former will rank highest on the whole, although the highest of the latter may surpass its lowest forms.

The *Zoophagous* subdivision will include the Bimana, Quadrumana, Carnivora, Insectivora, Cheiroptera, and Cetacea.

To the *Phytophagous* belong the Pachydermata, Ruminantia, Rodentia, and Edentata.

These last approach most nearly of the *Vivipara* to birds in the structure of their brains; but a still lower type is exhibited by the *Ovo-vivipara*, which are unquestionably the lowest of the Mammalia in point of *intelligence*.

Order I.—Bimana.

If we regard the possession of intellige peculiar characteristic of the class Mamma have no hesitation in selecting the order which Man alone belongs, as the *type* of being the form most unlike that of any ot on which this class borders. It has be pointed out, that there is an important con tween the high development of the bodily str of the intelligent powers of this class, and arity which distinguishes it from all others, prolongation of the period during which th dependent on its parent for support. And longation is greater in the human species, in to the whole length of life, than in any oth has evidently a direct connexion with the ult development of the mind and body of the off also a most important indirect influence on condition of the human race. Thus man, in the highest degree the characters which stated as distinctive of the Mammalia, is rig at the head of the class, although, as wil appear, he is surpassed by many other anima ticular portions of the bodily organisation.

The order Bimana includes but the sin *Homo*, or *Man*. Man is the only mammifero to which the erect position is natural, and in w is an essential difference in the organisation as of the two pairs of extremities. In those of th tribe whose form approaches most nearly t erect posture is not natural but constrained; of those agile movements so peculiar to the be exhibited, unless the body is supported well as behind. All the extremities of thes are alike formed as organs of prehension; in nivora, all are alike organs of prehension and in the hoofed animals, all are organs of suppo in man, the anterior or upper extremities are for prehension, and the posterior or lower ex support. When we examine these more par we observe that each pair is adapted to its p use in a higher degree than the extremiti monkey or any other animal. The foot of man and its surface expanded; and the leg bears upon it, the heel resting upon the ground. monkeys it is a sort of oblique continuation of as the hand of the arm, and supports the bo by its powers of prehension. The whole str the body is adapted to being exclusively supp the feet. The legs are so long, that man can he wished it, walk on all-fours; his short an inflexible foot, and his long thigh, would knee to the ground; whilst his widely-separat and his shoulders, which are but loosely att the trunk, would ill support the fore part of h

But by the adaptation of his whole fram erect posture, his upper extremities are left liberty, whilst his organs of sense are most fa situated for observation. The hand of man is to a far greater variety of purposes than th monkeys, in which it is most perfect. Its pe sists chiefly in the size and strength of the thum can have its tip brought into opposition with any of the fingers; and all these are capable moved separately. In none of the monkeys thumb be opposed to the fingers with any force, and in many their tips cannot be brou contact; so that, though admirably adapted ing round bodies of a certain size, such as branches of trees, their hands can neither minute objects nor support large ones. To th man some have attributed his superiority; b be safely said that he owes this to his mind a struments conjointly. The hand would be use out the mind to direct it; and mankind, if would soon be reduced to a very subordinate existence, if not speedily extinguished altogeth

Man, possessed of so remarkable a means

ı his mental ingenuity devises, is less pro-
rd both to acuteness of sensibility and to

e of his ingenuity, that his mental powers
led into active operation; and, when once
eir development has no assignable limit.*

*tailed inquiry into the characters of the different
tind, see the 4th number of the present series.

Order II.—Quadrumana.

The order Quadrumana, which takes its name from the peculiar conformation of the extremities of the animals composing it—all four of them having one of the toes opposed to the rest, like the thumb of man to his fingers—are remarkable for their facility in climbing, which they gain by the *grasping* power conferred upon them by the possession of *four hands*. Their anatomical structure refutes the common idea, that the upright position is natural to them; and it is certain that, though they may be taught in a state of captivity to walk erect like men, they usually support themselves by their anterior as well as their posterior limbs. It may be observed, that those species which approach the nearest to man rest upon the outer side of the foot only, and not upon its sole, when imitating his position; and that they are very insecure in it. And to those which are intermediate between the higher Quadrumana and the succeeding orders, the maintenance of the erect position without support for any length of time is impossible. It might be supposed that the possession of "four hands" is a character which raises the animals possessing it above two-handed man; but a little reflection will show that this is not the case, since the hand even of the highest Quadrumana is very inferior to that of man in complexity of structure and in the variety of movement to which it is adapted, whilst that of the lower shows but a slight advance upon the foot of the Carnivora. A corresponding series of gradations may be traced in the aspect of the face; for whilst, at one end of the series, the muzzle (at least in the young animal) is not much more prominent than it is in some races of man, at the other it nearly resembles that of other mammalia. Nevertheless, throughout the order, a certain degree of resemblance to man may be perceived, in the gestures as well as in the general aspect of these animals. All of them, like man and the Carnivora, possess three sorts of teeth; the canines, in the full-grown animal, are much more developed than in man; and there are intervals between them and the other teeth, which are not present in his jaws, but exist in all other mammalia.

Monkey.

The Quadrumana may be divided into three families —the Simiadæ, or Monkeys of the Old World; the Cebidæ, or American Monkeys; and the Lemuridæ, or Lemur tribe, which supply the place of monkeys in Madagascar and some parts of Africa and India. This restriction of distinct types of structure to different portions of the surface of the globe, is not a little remarkable; and it may be traced even in the subordinate divisions.

The Simiadæ include all the animals of the Old World known as apes, monkeys, and baboons—names which are commonly bestowed according to the development of the tail, the apes having none, the monkeys having a long one, and the baboons a short one. All these have *ten* molar teeth only in each jaw; and they have the partition between the nostrils very slender, so that the apertures are close to one another, as in man. On the other hand, all the Cebidæ are possessed of a tail, which is an extremely important organ to them, having great prehensile powers; they have *twelve* molar teeth in each jaw; and the partition between the nostrils is thick, so that the apertures are wide apart, as in the lower animals. The thumb of the hand, or fore foot, is not opposable; and it is entirely wanting in some of the genera. The Lemuridæ are distinguished from the monkeys, partly by the greater prolongation of the muzzle, the possession of a large bushy tail (which is not, however, prehensile), of opposable thumbs on all the feet, and of a crooked and pointed claw on

to man are to be found. Both these animals attain considerable size when full grown; probably in their native climate the former rising to five feet, and the latter to seven; but no living specimens of those sizes have ever been seen in this country. In both, there is a remarkable difference between the young and the adult form of the skull—the young bearing the greatest resemblance to that of man, whilst in the adult, the muzzle is so much prolonged, and the canine teeth are so much developed, as to give the face much more the aspect of that of the baboon. This difference, together with a change in the colour of the hair, has caused specimens of the orang, at different ages, to be accounted distinct species. The character of the animal also changes, being mild and gentle when young, but having a good deal of baboon-like ferocity when come to its full development. In the *Gibbons*, or long-armed apes, the length of the anterior members is so great, that they touch the ground when the animal is in a semi-erect attitude; these present an approach to the monkeys, in the possession of callosities on the buttocks by some of the species.

The *Monkeys* of the Old World are distinguished (in addition to the characters which separate them from the Cebidæ) by the possession of cheek-pouches, callosities, and a tail, which separate them from the apes; the tail is longer than in the baboons, the muzzle less protuberant, and the aspect less ferocious. The group contains, however, some species which present an approach to the apes, and others which form a transition to the baboons. The true Monkeys are also remarkable for the shortness of the arms in proportion to the legs, which causes some species to walk on all-fours with difficulty, climbing being their usual mode of locomotion; but, by common observers, they are still more noticed for the beauty of their colouring, their activity of movement, and gentleness of demeanour. Their character is much changed, however, by confinement. They are found in almost all the tropical countries of the Old World, and particular genera have a peculiar local distribution. Many of them live in societies, chiefly inhabiting the woods, but committing great devastations on any cultivated ground in the neighbourhood. In several species the aspect of the head is extremely grotesque, as are also the attitudes of the animal. The number of species is altogether considerable. Their food seems to be rather vegetable than animal; and in one genus this is distinctly indicated by the structure of the teeth and of the stomach. One genus, restricted to Africa, is destitute of thumbs on the anterior extremities, and the deficiency is partly supplied by the great development of the tail, which is not, however, prehensile, as in the American monkeys.

The *Baboons* have usually a short tail, or none at all; but there is much variation in this respect. They are rather distinguished from the apes and monkeys by the protuberance of the muzzle, and the ferocity of aspect which is partly dependent upon this; the canine teeth are generally large and strong. The Baboons have also a large bag connected with the organ of voice, by the resonance of which the power of their loud and discordant cries is greatly increased. In a state

Cebidæ are generally of smaller size than the
none of them attaining nearly the dimensio
chimpansee, orang, or mandril; they are
malicious, more easily tamed, and susceptible
constant attachment; but they seem to posse
telligence. They are found in very large nu
the woods of South America, where they chie
on vegetable food, to which their teeth show a
adaptation. The largest of them are the *A*
howling monkeys, which derive their tremendo
of voice from a sort of hollow drum connected
larynx (somewhat resembling that of the

others for their carnivorous propensities.

3. The third family of Quadrumana, that o
RIDÆ, has in many respects the general aspe
American monkeys; but the muzzle is much pr
resembling that of insectivorous or carnivor
mals; the teeth, also, are modified for anim
presenting sharp tubercles, locking into eac
and the grinding motion of the lower jaw is
so that its action possesses more of the scis
character of that of the animal-feeders. T
thumbs of these animals are well developed a
sable; the claw-like aspect of the nail of the f
finger has been already noticed as one of the m
recognised characters of the family. The ca
the lower jaw have the character of additional
and the first molars resemble the ordinary

species are known to exist, differing from ea
but little except in colour. On the other h
Galagos, which are found in the neighbourhoo
River Senegal, are pre-eminently insectivorous

This group is connected with the Chi
very remarkable animal—the *galeopithecus*, c
lemur, which so much resembles the bats, as
been placed with them by many naturalists
however, a *lemur* in all its essential character
has its limbs connected by thin skin, which they
out, as the framework of an umbrella supports t
ing. By this singular structure the animal is s
in the air, as by a parachute; but it has not th

sustaining a continued flight, though it can leap a
tance of a hundred yards with a gradual descent.
ke the bats, it feeds on insects, and sleeps with its
ad downwards, suspended by its hind legs. It is a
tive of the Indian archipelago.

Order III.—Cheiroptera.

The order Cheiroptera (formerly arranged by Cuvier
the first family of the order Carnaria) is perhaps the
st distinctly circumscribed group of the whole class
ammalia; for all the animals composing it agree in
possession of a pair of wings, formed by an exten-
n of the skin over the very elongated fingers of the
e legs, and connected also with the hind legs, by
ich they are adapted to raise and sustain themselves
the air, and also to propel themselves through it by
ular continued movements, in precisely the same
nner as birds. Now, although in other groups we
y observe a tendency towards the same adaptation,
s never carried farther than to give to the animal
sessing it the power of partially supporting itself in
air, so as to prolong its leaps, as is the case with
flying-squirrel, the flying-lemur, and flying-oposs-
n. None of these animals can really *fly*, like bats
l birds.

We see in the bats a very interesting modification of
whole character of the mammal, to enable it to lead
life of a bird, just as in the whale tribe we see a
ilar adaptation to the life of a fish. The insectivo-
s bats bear a strong analogy to the swallow, in the
racter of the food itself as in the mode in which they
ain it—by the rapid pursuit of insects on the wing;
chief difference in habit being the time at which
y respectively go forth in search of their prey.

The whole structure of the Cheiroptera is obviously
ted to the fulfilment of the object which is the dis-
uishing character of the group. All the bones of
upper extremity, as well as those which give at-
hment to its muscles, are very largely developed.
e member itself, although consisting essentially of
same parts as in man, has its aspect greatly changed
the extraordinary prolongation of the finger bones,
on which chiefly the skin of the wings is stretched.
is skin is extremely thin, and is generally devoid of
r on both sides. It extends not only between the
gers, but from the last finger to the posterior extre-
ty, and from this to the tail, where one exists. This
pansion of the tail probably serves as a rudder, en-
ling the animal to change its course rapidly in pur-
t of its insect prey—an idea which is supported by
fact, that in the bats which feed on vegetable sub-
nces, or on animals which require less activity of
suit, this part is either wholly wanting or is much
cumscribed in extent and power.

The four fingers of the anterior extremity being
olved in the expansion of the membrane, only the
mb is left free; this is of moderate length, and is
nished with a crooked nail, which is of great use to
e animal in climbing and making its way along the
ound. The toes of the hind feet are short, and fur-
shed with claws, by which the bats suspend them-
ves from the trees or walls on which they rest, hang-
g with the head downwards. They walk with slow-
ss and difficulty when placed on the ground; the
ngs are folded up; and they rest upon the hind feet,
d upon the claw of the thumb, by which they crawl
rwards, pushing on first one side and then the other.
t they can climb up perpendicular surfaces with
nsiderable agility. The expanded skin of the wings
pears to be endowed with a sensibility of a peculiar
nd, enabling the animals to perceive their proximity
solid bodies without the assistance of sight. That
ey have a very acute perception of this kind was long
o shown by the experiments of Spallanzani, who
und that bats deprived of sight, and, as far as pos-
le, of hearing also, were still capable of directing
eir flight with security and accuracy, finding their
y through passages only just large enough to admit
em without coming in contact with the sides, and even
avoiding numerous small threads which were stretched
across the room in various directions—the wings never,
even by accident, touching them. It is probably through
the vibrations of the air, which will differ according as
the wing strikes it in the neighbourhood or the absence
of any solid body, that the knowledge of the proximity
of such is communicated to the delicate and expanded
organ of touch. The use of this curious power to ani-
mals intended to execute rapid and varied movements
in the dark, and amongst trees, buildings, &c., is suffi-
ciently evident.

This tendency to a great extension of the skin is
manifested in other parts of the body. In many bats,
especially of the insectivorous kind, the external ear is
enormously developed; being, in the long-eared bat of
this country, nearly as long as the body. In the fru-
givorous bats, it is of ordinary size. The organ of
smell, too, in many of the insectivorous bats, is fur-
nished with curious leaf-like appendages, formed of the
integument doubled, folded, and cut into the most cu-
rious and grotesque forms. The group in which these
are most remarkable, is one which avoids the light of
day even more than others; the animals composing
it exist almost constantly in the darkest recesses of
caverns; and it is probable that, by this peculiar con-
formation, they gain increased power and delicacy of
the sense of smell, which in part compensates for the
inutility of the organs of vision.

The families composing this order, may be arranged
under two principal divisions, which are strongly con-
trasted with each other in regard to the nature of their
food, the conformation of their teeth and digestive
system, and the peculiarities of structure which are
connected with the mode in which food is obtained.
One of these groups, which may be regarded as typical
of the order, is insectivorous; the molar teeth are fur-
nished with pointed tubercles, as in the order Insecti-
vora; and the stomach and digestive system are evi-
dently adapted to animal food. The other group is
probably omnivorous, like many of the monkeys—feed-
ing chiefly on fruits, but pursuing small birds, or large
insects, that may be obtained without much difficulty;
their molar teeth have flattened crowns, adapted for
bruising and grinding their food; and the complex
structure of the stomach and intestinal canal shows its
adaptation to a vegetable diet. The proportional length
of the intestine, in specimens of these two groups, is a
remarkable illustration of this difference of adaptation.
In the great bat of this country, belonging to the former
group, it is only twice the length of the body; whilst
in the frugivorous *pteropus* of the tropics, it is seven
times.

The insectivorous group may be distributed into four
families:—1. Rhinolophinæ: in these, the nose-leaf
is of complicated structure, and is membranaceous;
the index or forefinger has but one joint; the wings
are large and broad. 2. Phyllostomina, which have
the nasal appendage simple and fleshy, and an index-
finger of two joints. 3. Vespertilionidæ, which are
destitute of nasal appendages, and have a single joint
in the forefinger. 4. Noctilioninæ, which are also
destitute of nasal appendages, but have two joints in
the index-finger.

1. To the first of these families, the Rhinolophinæ,
belong the greater and lesser *horse-shoe bats*, which are
found in the darkest and most secluded retreats of our
own country; their name is derived from the peculiar
form of the anterior nasal appendage. The family
contains many other genera and species, most of which
are inhabitants of the Old World.

2. To the second family, the Phyllostominæ, belongs
the celebrated *vampyre*, of the blood-thirsty propen-
sities of which such marvellous stories have been told.
The wound inflicted by its teeth is very small; but its
tongue is endowed with a peculiar power of suction,
by which a considerable amount of blood may perhaps
be drawn. There are no well-authenticated accounts
of the death of any animal having been occasioned by
this creature; and the story of its fanning its victim

with its wings to keep him cool, and render his sleep more profound, is probably a fiction of the imagination. Some of these bats have the tail very short, and in others it is altogether absent. They appear to feed in part upon succulent fruits; but there is one genus, the extreme shortness of whose intestine indicates that it must derive its food from animal matter almost exclusively. One of these has been taken in the act of sucking blood from the neck of a horse. The vampyres are confined to South America; but other members of this family inhabit the eastern hemisphere. Many of them attain considerable dimensions; the body being equal in size to that of a magpie, and the wings, when expanded, measuring between two and three feet across.

3. The third family, VESPERTILIONIDÆ, is by far the most numerous, and includes most of the bats of temperate climates. At least thirteen species exist in this

Long-eared Bat.

country, the largest of which is the mouse-coloured bat, the expansion of whose wings measures fifteen inches; but this is of rare occurrence. A more common one is the noctule, or great bat, which is but little smaller; this is often met with in considerable numbers, seeking its retreat sometimes in the hollows of trees, at others under the roofs and eaves of houses. Probably the most abundant is the long-eared bat, which is easily distinguished by the character implied in its name. Its ears are folded downwards during hybernation or profound sleep. It is easily tamed when in confinement, and may be brought to considerable familiarity, so as to eat from the hand. It has an acute and shrill but not loud cry.

4. The bats of the fourth family, NOCTILIONINÆ, are almost exclusively confined to tropical countries. The number of species belonging to this group is very large, but few of them present any important peculiarities.

5. The frugivorous or omnivorous group contains but one family, the PTEROPINÆ. This is widely diffused throughout warm climates, and contains some of the largest species of the order. It is not improbable that the fabulous harpy may have had its origin in some of these. None of them have the tail much developed, and in many it is entirely absent. The *pteropus Javanicus* is a very characteristic example of this family. It is probably the largest of the bats—its expanded wings measuring five feet across. It is extremely abundant in the lower parts of Java, and uniformly lives in societies. They suspend themselves from trees during the day; and, from their motionless aspect and contracted bodies, they might be mistaken for parts of the tree, or for fruit suspended from its branches. When night comes, they begin to move, and go in search of food to the forests, villages, and plantations, in all of which they do great mischief, attacking indiscriminately almost any kind of fruit, of which they devour a large quantity. In their turn, they are eaten by the human inhabitants of some of the countries where they abound, who consider them as delicacies. The flesh of the common rousette of the Mauritius has been compared to that of the hare and partridge.

The Cheiroptera, inhabiting temperate clim
remain in a torpid state during the winter.
them make their appearance, however, in mi
but as casual revivals during the season of r
injurious to them, they usually betake them
places of which the temperature is not readil
by external vicissitudes. The office of this
the economy of nature, is evidently to assist
restraining the too rapid multiplication of ins
to keep down the luxuriance of tropical veget

Order IV.—Insectivora.

The order Insectivora forms a group which
mediate between the Cheiroptera and the C
Like the greater part of the first-named of thes
the animals composing it are formed to live up
food; their molar teeth are beset with pointe
tubercles, adapted to crush the hard envelope
prey; and they are, for the most part, like t
nocturnal animals—like them, too, passing th
of temperate climates in a state of torpidity.
are completely destitute of the wing-like ex
which enable those animals to rise into the air
of their prey; it is *their* function to seek it u
ground, or even by burrowing beneath it. H
their general organisation, they more resemble
nivora; but they retain the clavicle (collar-bon
higher orders, which in the Carnivora is redu
ligament, and this affords, in the burrowing sp
very important attachment to the powerful mu
which their anterior members are put in actio

The teeth in this order are extremely varia
cannot be so safely followed as guides to class
as the general structure and habits. All the
belonging to it possess the peculiar conformatio
molars already described; the front molar, how
usually of a form adapted for cutting, like thos
Carnivora; but posterior to this, there are g
three with conical tubercles. The disposition
incisors and canines is very variable; in some
they are long, and in others short, and the f
all the teeth are often so much changed that it
cult to assign them to their respective classes.

This order may be divided into four families
are characterised by their habits as well as b
external form and internal structure. 1. TALP
Mole tribe. These are pre-eminently subter
and are distinguished by their extraordinary h
forming long and complicated burrows under
passing their whole lives in these retreats, in wh
are born, feed, breed, hybernate, and die. 2. SO
or *Shrews*. These are a sort of carnivorous mice,
though they do not actually burrow, retreat dur
winter, and in their ordinary repose, into hole
feed, however, on the surface or in the water,
of them being partially aquatic, diving with
after aquatic insects, and remaining without d
a long time under water. 3. ERINACEADÆ, or *Hed*
Here we have still hybernating animals, but in
burrowing or descending into deep excavation
conceal themselves at or near the surface, wh
find their food. The hair is converted into sp
considerable firmness. 4. TUPAIADÆ, consistin
single genus, the *Tupaia*. These partake of t
racter of the Insectivorous Quadrumana, living
which they climb with the agility of a monk
squirrel.

It is remarkable that, as far as yet known, no
of this order exist in South America or Austra
the former continent their place seems to be
by the Edentata, of which many species are s
their food and habits; and in New Holland t
replaced by numerous small Marsupialia, ha
same general adaptation of their structure t
food and to an underground residence.

1. Of the TALPIDÆ, the common English m
very characteristic example. The whole stru
this animal is beautifully adapted to the subt
life which it leads, and to the mode in which

TERRATA.

arkable not only for their covering of spines, but the great development of the muscular envelope of body immediately beneath the skin (especially on back), which in most other animals is scarcely perptible. By this they are enabled to roll themselves o a ball, presenting a panoply of sharp spines to their emies. These are not only strong enough to resist acks, but are sufficiently elastic to enable the animal throw itself down upon them from considerable ights. So that, although destitute of all means of nching its enemies or of defending itself by force, d not able to seek safety in flight, the hedgehog is dowed with a safeguard more secure and effectual an the teeth and claws of the wild-cat or the fleetss of the hare. In its natural state the hedgehog is cturnal, remaining coiled up in its retreat by day, d moving about all night in search of food. Its run quick and shuffling, and as it were by starts. Insects, rms, slugs, and snails, form the usual food of the dgehog; but it will also devour frogs, toads, mice, d even snakes; and has been known to feed on eggs d vegetable substances. It is easily rendered familiar th man and with other animals. Other species of is family connect it with the previous and succeeding oups, the spines not differing so much in size and ength from hairs, and the power of rolling up the dy being absent.

4. The last family, that of TUPAIADÆ, or *Banxrings*, is very remarkable one. It is confined to the Indian chipelago, and has not been long known to exist. eir teeth chiefly resemble those of the archiens, with slight tendency towards the lemurs; and, like this st group, their eyes are large and prominent. They e covered with hair, which is soft and glistening, but t fine in texture, and have a long bushy tail. Contrary the habits of other Insectivora, they ascend trees with e agility of a squirrel; from which animal, however, eir pointed muzzle renders them easily distinguishle, even at a distance. They are readily tamed, running freely through the house, and coming of themlves at every meal for fruit or milk.

Order V.—Carnivora.

The animals composing the order Carnivora are, like e four previous orders, separated from the other mmalia possessing distinct fingers by the presence three kinds of teeth; and from those orders they are stinguished by characters which point them out as pecially formed for the pursuit and destruction of rge animals. They possess in the upper and lower w six incisor teeth; a large, strong, and pointed nine tooth on each side; and molar teeth, which are idently formed for cutting and tearing rather than r bruising or grinding. The form of these teeth ries, however, in the different genera, in accordance ith their several habits. These molars consist of three nds: the anterior, immediately following the canines, hich are always more or less pointed, and are termed *se molars*; the next class, formed especially for cutng the flesh upon which the animals feed, are termed *rnivorous teeth*; and the posterior are tuberculated, ith flattened summits.

The proportion which these different classes bear to ch other in number and development, accords with e degree of the carnivorous propensity of the animal, d furnishes important characters in the subdivision the order. The more the surface of the molar teeth raised into points and edges, and the more the action the jaws is restricted to the scissors-like movement which these edges are made to meet and pass each her, the more purely carnivorous is the regimen of e animal: this is well seen in the Cat tribe. On the her hand, the more the molar surfaces are flattened, d the greater the lateral grinding motion of which the ws are susceptible, the greater is the probable admixre of vegetable food: this is seen in the bears. The neral structure of the body, and especially that of the tremities, is modified in a corresponding manner, in cordance with the habits and progressions of the ani-

mal. In all, the toes are furnished with claws, which are peculiarly sharp in the cats, and are in them kept ready for use within a sheath, from which they can be projected at the will of the animal. The stomach of the Carnivora is very simple in its form, and the intestines are short, in accordance with the easily digested character of their food.

The whole bony and muscular system exhibits a similar modification. Thus, whilst the powerful yet active and flexible movements of the purely carnivorous animals are adapted only to the pursuit and destruction of living prey, the more sluggish habits of most of the Bear tribe, their peculiar mode of progression, and the modified structure of the skull, the teeth, and the limbs, are all equally applicable to the mixed nature of their food. The difference in the conformation of the extremities, and in the mode of using them, is very striking in these two antagonised groups. In the former, the ends of the toes only touch the ground, the heel being considerably raised into the air; in this way, the limbs can be used to much greater advantage in running and springing: the animals possessing this conformation are termed *digitigrade* Carnivora. In the latter, the whole foot rests on the ground—a structure more favourable to the maintenance of a firm position, but preventing great activity of progression: these are called *plantigrade* Carnivora. There is a third very remarkable variety of conformation in the extremities of this order; and this is exhibited in the Seals. Here the anterior as well as the posterior feet are formed for swimming, being spread into fin-like paddles; and the whole arrangement of their organs is admirably adapted to the pursuit and capture of their scaly prey.

The Carnivora may be subdivided into five families, each containing a well-known form. 1. Felidæ, or *Cat* tribe. In these the destructive power is most highly developed. They are characterised by their short powerful jaws, their retractile claws, and the peculiar adaptation of their teeth for cutting. They have but one small flattened molar tooth above, and no corresponding one below. 2. Canidæ, or *Dog* tribe. These, like the cats, are digitigrade; but their claws are not retractile; and they have two flat tuberculated molars behind the great flesh-cutter. 3. Mustelidæ, or *Weasel* tribe. These are mostly semi-plantigrade, a portion of the sole touching the ground. They are distinguished by their long narrow bodies, and by the presence of only one tuberculated molar. 4. Ursidæ, or *Bear* tribe. These are the only true plantigrade Carnivora. Most of them possess several tuberculous teeth. 5. Phocidæ, or *Seal* tribe. These are at once distinguished by the adaptation of their form and structure to a residence in the water; and of their teeth for holding the slippery surface of fish, and crushing them before they are swallowed.

1. The *Cat* tribe includes a large number of animals very closely resembling each other in structure and aspect—so closely, indeed, that many of the species can only be distinguished by their size, and by the markings of their skin. They all agree, too, in the mode of catching their prey, which is to steal upon it unawares, and seize it with a sudden spring, in which they expend their energy, often slinking off when once baffled. It is very difficult to subdivide the family, on account of the strong general resemblance of its members. Most of them are sufficiently well known to render any peculiar description of them unnecessary. It may, however, be remarked, that some species are found in almost all tropical and temperate countries, and that those of different parts of the globe *represent* each other in a remarkable manner. Thus, the *lion* and *tiger* are inhabitants of Africa and tropical Asia; in America they are replaced by the *puma* and *jaguar*, which are confined to that continent. In the same manner, we find the *panther* and *leopard* spread over tropical Asia and Africa; the *caracal* inhabiting the Asiatic mountains; the *caracal* in India and Persia, and the *lynx* of Northern Europe. These are represented by the *ocelot* in South America, the *lynx* of Canada (differing from the European species) and other less known species. The Felidæ, like the noble falcons, will only eat the flesh of animals which have themselves killed, except when in a state of domestication or confinement, or when compelled by hunger.

Lion.

2. The family of Canidæ includes a much larger number of different forms, some of which approach to the Cat tribe, and others to the weasels and bears. This tendency to variation from a typical form is remarkably shown in the races of the common dog, which are believed to have all had the same origin, although the commencement of most of them is entirely unknown. The animals of this family agree in a greater or less adaptation to a mixed diet. All animal flesh naturally constitutes the principal food; all, they do not attack living animals with a degree of boldness proportional to their strength, and many of them feed upon carrion, sometimes even when much putrefied. The *wolves*, *foxes*, and *jackals*, animals which most nearly approach the dog; and the first of these it is regarded by many naturalists being really identical.

The *Hyænas* constitute a group remarkably distinct from the true Canidæ, and yet bearing enough characters to require to be associated with them. They are more purely carnivorous than the dog tribe, approach in the deficiency of tuberculated molars the cats. But they differ from these, not only in general aspect, which is much more nearly allied to the dog, but also in the absence of the retractile power of the claws, and in their propensity to feed on carrion. The teeth are peculiarly adapted for crushing, and their jaws are shorter than those of the dog, longer than those of the Felidæ. In many other points of structure, the hyænas are intermediate between the two groups. They are peculiarly ferocious animals, combining the persevering *doggedness* of the one with the furious bloodthirstiness of the other. Their habits are nocturnal—more so than those of most other Carnivora. Hyænas are now chiefly confined to Africa and the south of Asia; but there is no doubt, from the abundant remains of them which are preserved, that they must have formerly lived in large numbers in this country, and in other parts of Europe. To the Hyænas may be associated the *Civets*; the *ichneumon* of Egypt, which restrains the multiplication of crocodiles by feeding on their eggs.

3. The Mustelidæ are the most *bloodthirsty* of the Carnivora; but they are not so much addicted to devouring *flesh* as are the Felidæ. These animals, on account of the length of the body and the shortness of the limbs, which permit them to pass through small openings, are called *vermiform*. All the members of this family are semi-plantigrade; and they conduct us to the truly plantigrade Carnivora. The *weasel* of this country is a very characteristic example of the family; it is one of the most sanguinary, but confines itself chiefly to small animals, destroying large numbers of mice, rats, moles, &c. The *ferret*, which is an allied species, is bolder, having been known to attack man; and the *polecat* is a great enemy to the farm-yard, game-preserve, and warren. All these animals have a strongly and disagreeably odorous secretion from a pouch under the tail; but it is most disgusting in the last. The *Otters* constitute an aquatic form of this family, having the same general adaptation of dentition with the weasels, but being readily distinguished from all other genera of the family by their webbed toes and horizontally flattened tail. They feast on fish.

4. The true plantigrade Carnivora, consisting

f Ursidæ, participate in the comparative slow and nocturnal life of the Insectivora; and like o, the species which inhabit cold countries pass ter in a dormant state. In the *Bears*, the car- the nose is elongated and moveable, somewhat ing that of the Shrews. These animals possess facility, from the structure of the sole, of rear- nselves up on their hind feet; and this may be ly noticed in such as are, like the bears, fruit- becoming carnivorous only from necessity; they s enabled to climb trees in search of food. The re the largest of the family; and some species are pretty widely diffused over the globe. The , which resemble bears in miniature, with the n of the greater length of the tail, are confined ew world.

Badgers, *Tarels* or Badgers of America, and the *nes*, form a tribe connecting the Bears with the dæ. The *badger*, for example, is only semi-plan- and has a dentition very like that of the weasels ers, but adapted for a less carnivorous regimen. nas the tardy gait and nocturnal habits of the lantigrades; it does not, however, become tor- inter. All these animals, like the weasel tribe, e power of emitting a fetid odour at will.

ie last family, that of Phocidæ (the Amphibia er), is sufficiently distinguished from all the rest peculiar adaptation of the animals composing it rine residence. Their feet are so short, and so ed in the skin, that they are of little use in pro- on land. In fact, the seal employs them only lambering, wriggling itself forwards along a rface by the action of the abdominal muscles. ervals between the toes are occupied by mem- so as to convert the feet into oars. The body hened, and the spine very flexible, as in the and Fishes; and the animals are covered with close fur, sitting flat upon the skin. All these ions combine to render them able swimmers; y pass the greatest part of their time in the which they only quit to bask in the sunshine uckle their young.

ie two genera, the *Seal* and the *Morse*, which ily contains, the former presents the least de- from the general type of the order, being , as to its teeth and digestive organs, for animal ie latter group is chiefly herbivorous.

Order VI.—Cetacea.

e order Cetacea, or *Whale* tribe, the adaptation mammiferous structure to the life of a fish is markably displayed. The whole body is formed exclusive residence in the water. The posterior ities are no longer present, as in the seal, to a progression on land; nor are the toes of the furnished with claws. The trunk is prolonged hick tail, which terminates in a horizontal car- us fin, by the vertical movement of which the ion of the body is effected. The head is very nd is connected with the body (as in fishes) by so d thick a neck, that no diminution of its circum- is perceptible; and the cervical vertebræ, which l (as in all Mammalia) seven in number, are in, and partly united together. The bones of and fore-arm are very short; and those of the e flattened, and enveloped in a tendinous mem- which reduces them to the condition of fins. their whole aspect is that of fishes, except that e not covered with scales, and that they have -fin expanded in the contrary direction. The of this last provision is to enable them more to come to the surface to breathe, which they iged frequently to do. The largest species can , however, for an hour under water. Their blood, t of other Mammalia, is warm; and to prevent nal temperature from being rapidly lowered by ducting power of the water, they are furnished thick coating of fat over the whole body. There are never any external ears, nor hairs upon the body. In these general characters, some other whale-like animals, now separated from the true Cetacea, agree; but they differ in being adapted for vegetable food, whilst the true whales are all animal-feeders, and are, therefore, properly associated with the Carnivora, to which they make a near approach through the seal. It is evident that the want of claws should not exclude them from this division of the Mammalia, since these are rendered useless by the adaptation of the animal to an exclusively aquatic residence. Some of them, which feed upon large marine animals, seize their prey with their jaws, whilst others, which derive their support from the smaller kinds, engulf them, with a large quantity of water, in their capacious mouths.

The true Cetacea are further distinguished from those herbivorous forms which are now associated with the Pachydermata, by the remarkable conformation from which they receive the name of *Blowers*. As with their prey they necessarily take in a great volume of water, a means of getting rid of this is required, and it is accordingly transmitted through the nostrils, and expelled by a strong muscular action through a narrow aperture pierced at the summit of the head. It is thus that these animals produce the jets by which they are observed at a great distance. Their nostrils, being continually bathed in water, are not adapted to a delicate perception of odours; and their organs of hearing, being deficient in the external ear, and otherwise formed on a lower type, are also probably incapable of very acute perception of sound. But what is deficient in these respects seems to be compensated by a very high degree of sensibility of the general surface; and there is reason to believe that, by this diffused sense, whales are enabled to take cognisance of what passes in the water at a considerable distance, through the medium of the vibrations excited in the fluid.

In subdividing this order, the *dentition* does not afford much assistance, for the teeth are frequently absent altogether; and among the species which possess them, they often exhibit great differences, when the animals are closely allied. Where they exist, they are mostly small, numerous, and of a conical form, similar to each other. These animals do not chew their food, but swallow it whole. The stomach is usually of a rather complex form. The order may be divided into two families, according to the relative size of the head and body. In the first, Delphinidæ, or the *Dolphin* tribe, the head is not out of the usual proportion; in the second, the Balenidæ, or *Whale* tribe, it is immoderately large.

1. The Delphinidæ have teeth throughout both jaws, all simple, and nearly always conical. They are the most carnivorous, and, in proportion to their size, the most cruel of their order. The common *dolphin* has its snout prolonged into a kind of beak. It is extremely agile in its movements; and a number are often seen sporting together on the surface of the water. Nearly allied to the dolphin is the *porpoise*, which has a short muzzle. This is one of the smallest of the Cetacea, not exceeding four or five feet in length, and is very common in various parts of the Atlantic, assembling in vast herds. Allied to the porpoise is the *grampus*, which has large conical teeth, and is the most powerful of this family, attaining the length of from twenty to twenty-five feet. It is a cruel enemy to the whale, which it attacks in troops. Other species of this family are known on our coasts by the names of *white whale*, *bottle-nose*, *narwhal* or *sea-unicorn*, &c. This last animal is remarkable for the enormous development of a single tooth or tusk, commonly reputed to be a horn, whence the name commonly given to the species. In the general form of the head and body it agrees closely with the porpoises; but it possesses no other teeth than this tusk, which projects forwards, apparently from the centre of the upper jaw, to the length of ten feet. The animal really possesses, however, the germs of two tusks, of which only one is generally developed. That on the left side usually attains its full growth, whilst

the other remains permanently concealed within its socket.

2. The remaining Cetacea, constituting the family Balænidæ, have the head so very large as to constitute one-third, or even one-half, of the entire length; but neither the cranium nor the brain participate in this disproportion, which is entirely due to an enormous development of the bones of the face. This family contains several remarkable and important animals, amongst which the following may be noticed:—The *catodon*, or spermaceti whale, receives its technical name from possessing teeth in the lower jaw only; these are of considerable size, and lock into cavities in the upper jaw when the mouth is closed. The superior portion of the enormous head consists almost entirely of large cavities, separated and covered by cartilages, and filled with an oil that concretes in cooling, and is known by the name of spermaceti. This is commonly, but erroneously, reputed to be the brain of the animal; the cavities which contain it, however, are very distinct from the true cranial cavity, which is rather small, and lies at the posterior portion of the head. Cavities containing spermaceti are found in various parts of the body, even ramifying through the external fat or blubber, and these communicate with those in the head. This whale is extensively distributed through various seas, but chiefly abounds towards the antarctic region. It sometimes attains the length of seventy feet.

The *balæna*, or Greenland whale, equals the catodon in size and in the proportional length of the head, which is not, however, so much enlarged in front. Instead of teeth, the mouth is provided with a number of vertical plates, terminating in fringes, which are composed of a sort of fibrous horn, and may be regarded as a kind of prolongation of the gum. These fringed plates, commonly known as whalebone, serve to retain, by straining from the water, the minute animals on which these enormous beings subsist. Their food consists partly of fishes, but chiefly of soft mollusca, acalephæ, &c. The blubber is of immense thickness, and furnishes a large quantity of oil—a hundred and twenty tons being sometimes obtained from a single individual. The whalebone also is an important object of pursuit. This animal was formerly not very uncommon in our seas, but has now retired to the far north, where its number, in consequence of the attacks of man, is constantly diminishing. The *rorqual*, an allied species, attains to still greater size, having been seen of the length of a hundred feet.

animals of the small family Chinchillidæ l recently known only by their skins, which an important article of commerce. In their ganisation they seem intermediate between and rabbits, but differ from both of them in clavicles. They are all natives of South chiefly inhabiting the range of the Andes, ive socially, in extensive burrows.

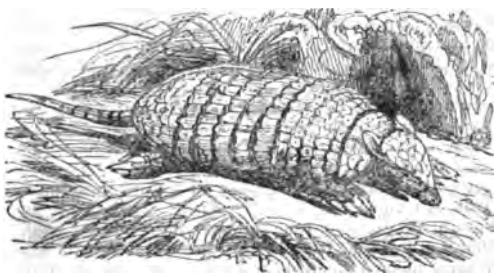
Leporidæ constitute the last family of the and are distinguished from the rest by the f two small incisors behind the rodent teeth. and habits of the typical genus, *Lepus*, are well known in the *hare* and *rabbit* of this A large number of species exist in the diffe- of the northern hemisphere, and some are a of the Arctic regions. There is one species ntry, in which the brown fur, that forms its oat, changes to white at the approach of he hare is a ruminating animal, though with- uliarly complex stomach of the Ruminantia.

Order VIII.—Edentata.

mals composing the order Edentata cannot ed by any general positive characters which hem from other groups; for there is a con- lissimilarity in the entire structure and habits erent species. The chief point of agreement em is a negative one—the absence of incisor the termination of the extremities in hoof,

white ants), whence these insects are withdrawn by being entangled in the viscid saliva that covers it. Their fore-nails, strong and trenchant, enable them to tear open these nests, and also furnish them with an effective means of defence.

Most of the other true Edentata are burrowing animals, and are covered with a dense armour, composed of hard scales arranged in a *tesselated* manner, or fitted together like stones in a pavement. Between the different bands of these, there are narrow rings of membrane, which allow the body to bend. They have claws adapted for digging, seven or eight cylindrical molars on each side, and a tongue but little extensible. Of these animals the *Armidillos* are the chief, and are the forms best known. They subsist partly on vegetables and partly on insects and carcasses. Some of them appear to prefer putrefying animal matter; and many are nocturnal feeders.



Poyou or Six-banded Armadillo.

2. The animals belonging to the family TARDIGRADA are at once known from the true Edentata by the peculiar shortness of the muzzle. The name of the family is derived from that commonly applied to the animals composing it. In the *Sloths*, according to Cuvier, "nature seems to have amused herself with producing something imperfect and grotesque." And if we consider the peculiarities of their organisation in reference to the ordinary habits of mammiferous animals, this an-

habitation removes them out of the reach of voracious animals, by which the race might be extirpated.

There have been found in South America try to which the existing Edentata are als —remains of some enormous extinct anim ing evidently to the same group. Of one *megatherium*, nearly the whole skeleton h studied, by comparing different imperfect and there can be little doubt that it belo gantic animal intermediate between the sl eaters. Its haunches must have been ne feet wide; and its body fourteen feet lon high. Its feet were a yard long, and te gigantic claws. Its whole structure seems adapted to digging the earth in search of t roots which probably constituted great par Another extinct animal of the same descript by little else than its claws, and fragments teeth. From the form of the claw, the s it has been named) was at first supposed nivorous animal; but Cuvier satisfactorily belong to the Edentata. It seems nearly megatherium. Remains of tesselated bony also been found, which indicate the former a large animal allied to the Armadillos, name *glyptodon* has been given; and othe gigantic ant-eaters have lately been disco same locality.

The Edentata terminate the series of the or *clawed* true Mammalia; and, as has be there are some among them with the cla and so enveloping the ends of the toes, duced to so small a number, as to appro nature of hoofs. ZOOLOGY—(CONTINUED).

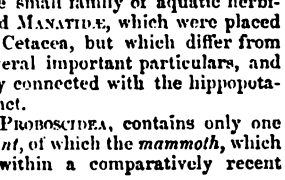
Order IX.—Pachydermata.

chydermata, consisting of hoofed ani- not ruminate, may be divided into three f which shows a tendency towards some The first of these, PROBOSCIDEA, contain- *lephant* and its extinct congeners, ap- veral particulars to the Rodentia. In ro large front teeth developed at the ex- st, and the grinders are formed of paral- amel and bony matter. There are also resemblance in the form of the bones, icularly in those of the extremities. For as not a complete hoof, but five toes to ch are very distinct in the skeleton; but l in a callous skin, which surrounds them ternal indication of their separate condi- nails at their extremities. The second RUE PACHYDERMATA, contains those which ee, or two toes to their feet. Those in make even numbers, as the SUIDÆ, or feet somewhat cleft, and approximate ntia in various parts of the skeleton, and plication of the stomach. Of the others, cloven feet, some approach the Probos- ich they are connected by forms now ex- hich the bony remains are sufficient to r character. The third group of Pachy- OLIDUNGULA, consists of quadrupeds with ent toe, and a single hoof to each foot, These also, in their general form and , approach the Ruminantia, with which cularly connected by the camel and an tinct. Another group should also pro- iated with this order, holding the same the Amphibia or Seal tribe among the his is the small family of aquatic herbi- , termed MANATIDÆ, which were placed ng the Cetacea, but which differ from s in several important particulars, and e closely connected with the hippopota- ow extinct.

group, PROBOSCIDEA, contains only one e *elephant*, of which the *mammoth*, which extinct within a comparatively recent ied spe- extinct group is which, ation of ears to ity with us. All agreed pair of



Elephant.

s or front teeth, and a very elongated oscis; and it is probable that this last organ was formed, as in the elephant, to answer the purposes of a hand, laying hold of large objects by coiling itself round them, and of small by means of the finger-like organ at its extremity. The magnitude of the sockets necessary to hold the tusks, renders the upper jaw so high, that the nostrils, which are prolonged through the trunk, are placed in the skeleton near the top of the face. By means of its trunk, the elephant not only lays hold of its food, but sucks up its drink, which it makes to fill its capacious nostrils, and then discharges, by bending its trunk, into its mouth. By this admirable organ, the shortness of the neck, rendered necessary by the weight of the head, is fully compensated. The cavity for the brain by no means corresponds with the external form of the skull; for, in order, as it would seem, to give a larger surface for the attachment of the muscles of the trunk, the outer layer of bone is widely separated from the inner, and between the two are a number of large bony cells.

In none of the Proboscidea has the lower jaw of the adult any front teeth. The arrangement of the grinders differs in the various species; but in all they are composed of alternating plates of hard *enamel* and softer *bony* matter, cemented together by a third substance, which is termed the *cortical*. These grinders are in constant progress of renewal; but they succeed each other, not by rising from below upwards, as in man, but by being pushed forwards from behind, in proportion as the tooth before each is worn away. There is never more than one *perfect* molar on each side; but in proportion to the age of the animal there may be two, three, four, or more, the front ones being the worn-down remains of those at first formed. It is stated that the molars are thus renewed eight times. The tusks, however, are only changed once; but, like the cutting teeth of the Rodents, they are constantly being renewed at the roots. Two species of elephants exist at the present day, both of which inhabit tropical climates, one in Asia the other in Africa. Remains of the mammoth are chiefly found in the north of America and of Siberia; and, from a nearly perfect specimen, which was discovered frozen in the ice near the mouth of the River Lena, it appears that this species was adapted to live in cold climates—the skin being densely covered with hair of two kinds. The habits of the elephant are sufficiently well known to render it unnecessary here to dwell on them. Its food is entirely vegetable; and, in its undomesticated state, it consists chiefly of the leaves and young branches of trees, and of the long herbage of the ground, both of which it gathers with its trunk. The tusks serve not only as weapons of offence and defence, but to root up small trees and tear down cross branches, either to obtain their leaves, or to make a passage for the bulky body of the animal through the tangled forest.

2. Of the true Pachydermata the first family is that of SUIDÆ, the *Pig* kind. It is characterised by the

peculiar thickness of the skin, and by the presence of four toes on each foot. They have three sorts of teeth in each jaw; the canines are usually long, and project forwards as tusks; the anterior molars are more or less narrow and conical, whilst the posterior are tuberculated. The food is principally vegetable, but admits of considerable variation. The domesticated pig is well known to be quite an omnivorous animal. In the true pigs, the foot has two toes furnished with large hoofs, and two much shorter ones that scarcely touch the ground. The *wild-boar*, which abounds in some parts of the continent of Europe, is well known to be a very ferocious animal; and the domesticated race which is derived from it often exhibits indications of the same character. One of the most curious animals of this tribe is the *babyroussa*, a native of the Indian archipelago; the upper canines of which are very long, and grow spirally upwards and backwards. These serve as defensive weapons of a very powerful description, inflicting severe lacerations by an upward stroke of the head.

With the family of Suidæ is probably to be placed the *hippopotamus*, or river-horse, which seems in many respects intermediate between the pig and the elephant; whilst its aquatic habits, and the conformation by which it is adapted to these, approximate it to the Dugongs. Only one species is known, which is now confined to the rivers of middle and south Africa. But for its short, thick, and very blunt muzzle, it might be compared to a gigantic pig; the body is extremely massive, and the legs so short that the belly almost touches the ground; and it is destitute of any covering but a few weak and scattered bristles. The canine teeth are long; the upper ones straight, and the lower curved backwards, so that they rub against each other. Although ferocious, or rather courageous, when attacked, these unwieldy inhabitants of the waters are in their nature shy, and feed entirely on roots and other vegetables, seeming to prefer those which are partially decomposed by the action of the water.

3. The second family of true Pachydermata, to which the name of TAPIRIDÆ, or the *Tapir* tribe, may be given, resembles the first in the thickness of its skin, but differs in the arrangement of the toes, of which there are only three on each hind foot, and sometimes also in front, without any central cleft. There is considerable variation in regard to the teeth; but the whole family is exclusively herbivorous. No members of it exist in Europe at the present time; but fossil remains of very large species are abundant in some localities. The *tapir* of America is about the size of a small ass, with a brown and almost naked skin, a short tail, and fleshy neck that forms a crest at the nape. It is common in humid places and along the rivers, and its flesh is eaten. The nose assumes the form of a short fleshy trunk—the rudiment, as it were, of that of the elephant. Other species have been recently discovered of a larger size; one of which has the bones of the nose still more elongated, approaching a very remarkable fossil genus, the *palæotherium*.

Form of Palæotherium.

This seems to have been an animal nearly allied to the Tapirs; remains of several species, varying in size from a rhinoceros to a small sheep, have been found in the gypsum quarries of Paris, the fresh-water deposits of the Isle of Wight, and other places.

To this family belongs the *rhinoceros*, which is remarkable for its large size, and for the kind of horn, composed of a solid fibrous substance, resembling agglutinated hairs, which is supported on an arch formed by the nasal bones. Several species exist in different parts of the tropical portion of the Old World. They are naturally stupid and ferocious, frequenting marshy places, and subsisting on herbage and the bra trees. In some species a second horn exists b first. The upper lip is generally elongated, some power of prehension. Rhinoceros' b been disinterred in many parts of Europe.

4. The third group of Pachydermata, the GULA, contains only one family, that of the H *Horse* tribe. Though there is only one app and single hoof to each foot, there are appea neath the skin which represent two lateral t well-known animals of this tribe, the *horse*, *quagga*, *onagga*, and *dzegguetai*, are commonly as belonging to but one genus; but the first probably to be separated from the rest, from cumstance of its tail being wholly clothed hair, whilst that of the rest has long hair onl the tip. On this point, however, there is muc tainty, arising from our ignorance as to the stock of the horse. In all the instances in at present know horses to exist in a wild state, appears to have been originally derived from ticated stock. This is certainly the case wit to the wild horses which now spread over the South America, all of which are descended fr first introduced there by the Spaniards.

All the animals just named agree in their There are six incisors to each jaw, which youth, have their crowns furrowed by a gro six molars on each side, above and below, wi crowns, marked, by plates of enamel which them, with four crescents. The males have, in two small canines in their upper jaw, and s in both; these are always wanting in the fem tween the canines and the first molar there space, which corresponds with the angle of where the *bit* is placed, by which alone man enabled to subdue these powerful quadrupeds of the species of this family are indigenous rica.

5. The animals associated in the family A may be considered as Pachydermata still more than the hippopotamus to an aquatic reside their teeth and general organisation they bea correspondence to this order; and the fish-l which they exhibit is scarcely a greater varia is seen in the order Carnivora. The posteri nities of these animals are entirely wanting, true Cetacea. The type of this family is the which grows to the length of fifteen feet, and f the mouths of the African and American rive called sea-cow, and its flesh is eaten.

Order X.—Ruminantia.

The order Ruminantia is perhaps the most and best determined of the whole class, fo species which compose it seem constructed, as upon the same model, the camels alone presen considerable exceptions to the general charact group. The first of these characters is the a sence of incisor teeth from the upper jaw; w lower appears to possess eight; of these, how two outer ones are really canines which have t form of incisors, so that the number of the tru is six, as in the other viviparous Mammalia. lars are almost always six in number, both a below, and have their crowns marked with tw crescentic ridges of enamel, which aid in th the food. The feet are each terminated by and two hoofs, which present a flat surface other, appearing as though a single hoof had b hence the names that have been applied to t nals, of cloven-footed, &c. Behind the hoof always two small spurs, which are the vestiges toes.

The name of the order intimates the singula possessed by these animals, of masticating the second time, or "chewing the cud." This fa pends on the structure of their stomachs, w four in number. The food which is croppe

y die, and fall from the skull; and the animal
defenceless. Others, however, are reproduced,
y larger than before, which are destined to
the same fate. These horns, periodically re-
are usually styled *antlers*.

Ruminants with horny sheaths to the bony pro-
s, may be divided into three families. Ante-
or *Antelope* tribe, characterised by the light-
their forms and the activity of their movements,
the solidity of the bony cure. Capridæ, or *Goat*
n these the bony core is partly occupied with
nd the general form approaches that of the Ox
ut the horns are directed upwards and back-

l upwards and forwards; the form is robust, and
resents heavy. The division of the Ruminants
h the horns are periodically cast off, constitutes
e family, that of Cervidæ, the *Stag* tribe. An-
mily, including only the giraffes, and named
ramidæ, is characterised by the shortness and
ture of the horns, which are covered with a
Of the Ruminants without horns there are two
families—the Moschidæ, or *Musk Deer*, which
markable for their elegance and lightness, and
ut little from the rest of the order save in the
of horns; and the Camelidæ, or *Camel* tribe,
in their dentition and in the structure of the
ities, exhibit a transition to the Pachydermata.

e family Antelopidæ, remarkable for the elan-
of form and swiftness of foot of the animals
ing it, contains above seventy well-ascertained
bearing a strong general resemblance to each
Most of these are natives of Africa; a few
however, inhabit Asia; a still smaller number
America; and one only, the *chamois*, now re-
n Europe. Among these numerous species we
ith forms that remind us of the other families
Ruminantia—the ox, goat, stag, &c. They gene-
sociate in large herds, which migrate together
ch of pastures. A species well known to the
s of South Africa is the *spring-bok*, which oc-
lly visits their cultivated lands, during seasons
ght, in innumerable herds, causing devastation
er they pass. The antelopes may probably be
d as the types of the Ruminantia, exhibiting
ular characters of the order in the most remark-
gree. They are extremely vigilant and timid;
speed of the swiftest species surpasses that of
other mammiferous animal. Those which are
d to live on rocks and mountains exhibit the
markable agility, and fearlessness of those dan-

Spring-bok Antelope.

hich their habits would seem to involve; they
with perfect composure along the giddy brinks
most awful precipices, climb and descend with
rful care and precision, and leap up or down to
allest surface that will contain their collected
ith perfect firmness; and yet they are so fearful
supposed enemy, that it is difficult to get within
t of them.

he family of Capridæ is connected with the last
ny antelopes which, like the chamois, approach
ats in form. It includes only the goats and sheep,
riginal stock of the domestic breeds of the former

appears to be indigenous to Persia, where it inhabits the mountains in large troops. The goats of Angora, Thibet, &c., celebrated for the fine quality of their hair, are no more than varieties of the common species. The *ibex*, which inhabits the mountains of the old world, and especially the Caucasian chain, is distinguished by the size and strength of its horns. It is said that this animal fearlessly precipitates itself down precipices, always falling on its horns, the elasticity of which secures it from injury. The *sheep* appear to have extremely little real difference from the goats: a large number of races exist, the relation of which to each other is uncertain; and there is doubt as to the original stock of the whole. Of the domestication of this animal we have an earlier record than of any other.

3. The species of the family Bovidæ, or *Ox* tribe, are comparatively few. They are all large animals, with a broad muzzle, heavy and massive body, and stout limbs. Of the original stock of the domestic ox, we have no certainty, since, as in the case of horses, the existing races of wild-cattle are probably all descended from those which have been at some period subservient to man. Of all the animals which have been reduced to his service, the ox is, without exception, that to which he is most indebted, for the extent and variety of its means of usefulness. The universal utility of the animal appears to have been very soon detected; and we find, consequently, that its domestication soon followed that of sheep, and that it is mentioned in the most ancient records as a servant of man, long before either the horse or dog are noticed.

Amongst the undomesticated species of this family, which have all a strong general resemblance to each other, and are the most powerful and savage animals of the whole order, may be noticed the European *bison*, which was formerly spread over Europe, but is now restricted to Lithuania and the Caucasian region; the American bison, commonly called *buffalo*, which inhabits all the temperate parts of North America; the *Indian buffalo*, of which there are several different races (in one, the horns include a space of ten feet from tip to tip), of which some have been domesticated; the *Cape*

Cape Buffalo.

buffalo, an extremely ferocious animal, with large horns, first directed downwards so as nearly to cover the forehead, inhabiting the woods of Caffraria; and the *musk-ox*, a species inhabiting the coldest regions of North America, with short legs, and long hair reaching the ground, which diffuses more strongly than the rest the musky odour common to the whole genus, and which is particularly noticeable in the European bison.

4. *The family* Cervidæ, or *Stag* tribe, includes, like *that of antelopes*, a large number of species differing *but little amongst* each other, very widely diffused over *the earth's surface*, and easily separated from others *by the character of* the horns. With the exception of the reindeer, however, the female is destitute save in a few rare individual cases, analogous in which the hen assumes the plumage of the The substance of the horns, when completely is that of a dense bone, without pores or inter their figure varies greatly according to the sp even in the same individual at different age animals are extremely fleet, and live mostly where they feed on grass, the leaves and trees, &c.

5. Of the family Camelopardæ, only one sp for a long time known to exist; but there are two, or even three, kinds of giraffe, all of natives of Africa, frequenting chiefly the b the deserts. Its remarkable form, dependin on the great length of its neck and fore legs, i to every one. In its general structure, ho closely resembles the deer; differing from th permanence of the horns. It has also some affinity to the camels; especially in the long neck, the existence of callosities, or hard sur the breast and knees, and the absence of t spurious hoofs. It is the tallest of all animals; being frequently raised eighteen feet from the Its disposition is gentle, and it feeds on leaves ing upon the young branches at a height mos that which any other animal can reach, and them towards its mouth by its prehensile tong lives in small troops of five or six individuals very timid, although capable of powerfully de itself by kicking. Notwithstanding the lengt neck, the number of vertebræ which this part a is no greater than in other Mammalia.

6. The Moschidæ, or *Musk-deer*, are compos termediate between the true *Deer* and the Cam which last connects the Ruminantia with the dermata. They resemble the ordinary Rumin the lightness and elegance of their forms, and nimbleness of their movements; and differ ch the absence of horns, and in the projection of the tooth on each side of the upper jaw, as in the The name of this group has been derived fr common Musk, the males of which secrete the ferous substance so called. This species is almo out tail; and the hairs which completely cover so coarse and brittle that they might almost be spines. It is confined to the mountainous reg tween Siberia, China, and Thibet, from which the Asiatic rivers descend. Its habits are no and solitary, and its timidity extreme. The musk-deer inhabit the warmer parts of Asia eastern archipelago; they have no musk-pouch are the smallest and most elegant of the Rum and are active and gentle in their habits.

7. The Camelidæ, or *Camel* tribe, approxima preceding order, and especially to the whole-ho sion of it constituting the Horse tribe, more tha other Ruminants—to such a degree indeed, th naturalists prefer associating them with tha They have always canines in both jaws, and t incisors have also the same pointed shape. mals of this family are much less elegant in f graceful in action than the other Ruminants; organisation is, equally with theirs, most adapted to the circumstances in which they ex family contains two groups, the *Camels* and *Lla* former are restricted to the Old World, and correspond to them in the New.

In the true *Camels* the two toes are united a kind of horny sole, almost to their points, w minate in small hoofs; and there is a soft cu neath the foot, by which it bears upon the su face over which it is formed to move. Two sp known, one called the *Bactrian* or *two-humpe* and the other the *Arabian*, or *one-humped*. completely domesticated. The first is employe in Central Asia, the latter in Arabia, North Syria, Persia, &c. The two-humped camel is and stronger, being capable of sustaining

Order XI.—Marsupialia.

naining orders of Mammalia, the Mar-
onotremata, are now usually regarded as
distinct sub-class, termed *Ovo-vivipara*,
etween the truly viviparous Mammalia
ous Birds and Reptiles. Their most ob-
ty is the production of their young at a
od of development, in a state incapable of
rely exhibiting the rudiments of limbs;
t until a long time after their birth that
condition parallel to that of a new-born
of the higher orders, and they much
the half-formed chick in an egg which
few days incubated. In accordance with
le of this important function, we find a
rity of the whole organisation to that of
parous Mammalia, and approaches, in
structure, to birds and reptiles. The
ervous system, the arrangement of the
sels, and the larger number of the incisor
the higher sub-class never exceed six),
ations of this approximation; and this
d in the deficiency of intelligence, which
their physiognomy as well as in their

) orders, that of Marsupialia is the one
the least departure from the general
mmalia, and it is that, too, in which the
he continued nourishment of the young
s the most remarkable. The new-born
ring attaches itself to the teats of the
nains fixed there until it has acquired a
lopment comparable to that with which
are born. The skin of the abdomen of
) disposed as to form a pouch, in which
t young are protected, and into which,
long after they can walk, they retire for shelter on the apprehension of danger. It is from the pouch (*marsupium*) that the order takes its name, this being its distinguishing peculiarity. It is remarkable that, notwithstanding the general and usually very striking resemblance of the species to each other, they differ so much in the teeth, the digestive organs, and the feet, that, if we rigidly adhere to these characters, we should find it necessary to separate them into distinct orders.

The geographic range of this order is extremely peculiar. With the exception of the Opossum group, which inhabits America, its species are at present almost confined to Australia and the neighbouring countries, where they constitute, with the Monotremata, almost the only mammiferous animals.

The Marsupialia may be divided into families according to the nature of their food. Some of those inhabiting Australia are altogether carnivorous, and display considerable ferocity. The *Opossums* have a mixed diet; they are remarkable for possessing an opposable thumb, like that of Quadrumana. Another group is more formed to live in trees, where they feed upon insects and fruit; to this belongs the *petaurus*, or flying-opossum, which is formed upon the same plan with the flying-lemur. The *Kangaroos*, of which several species exist, resemble

Great Kangaroo.

the Ruminantia in food and habits. They are remarkable for the enormous length of their hinder feet, whence their generic name, *Macropus* (long-footed), is derived. The hind legs and tail are also very largely developed; whilst the fore legs and feet are very small. From this great inequality in the size of the limbs, they advance on all-fours very slowly; but they can make immense leaps with the hind legs, the tail probably assisting them. These are furnished with one large nail, almost like a hoof, which is a powerful weapon of offence and defence; for, supporting itself upon one leg and its tail, the animal can inflict a very severe blow with the leg which is at liberty. It will sometimes grasp its enemy with its fore paws, whilst it kicks it with its hind foot; but this it will only do when attacked, for it is naturally a very gentle animal. The largest species is sometimes six feet in height, having the bulk of a sheep, and weighing 140 lbs. Its flesh is used as food by the New Hollanders, and is described as being a little like venison.

Order XII.—Monotremata.

The order Monotremata is a very extraordinary one. It contains but two species, the *echidna* or spiny ant-eater, and the *ornithorhyncus* or duck-billed platypus; and these are found nowhere else than in New Holland and Van Diemen's Land. These were included by Cuvier (who regarded the absence of teeth as the chief character) amongst his Edentata; but zoologists have now generally agreed that the peculiarities of their structure and physiology fully entitle them to rank as a distinct order, even more dissimilar to the other Mammalia than are the marsupial quadrupeds just considered.

this is a point of very remarkable affinity with that class, which is borne out by their general organisation. There is a sort of clavicle (collar-bone) common to both shoulders, placed before the ordinary clavicle, and analogous to the *furcula* (merry-thought) of birds. Each foot possesses five claws; and, besides these, the males have a peculiar spur on the hinder ones, like that of a cock.

The *Echidna* is characterised by the slenderness of the prolonged muzzle or bill, which contains an extensible tongue, like that of the ant-eater. The feet are short, very robust, and adapted for digging. The whole upper part of the body is covered with spines, bearing some resemblance to those of the hedgehog; and, when apprehensive of danger, and unable to escape from it by burrowing, the echidna can erect its spines, and roll itself into a ball.

The habits of the *Echidna* in a state of nature are but little known; for they do not exist in any large number; and they burrow so rapidly in the ground, that, even when one is discovered, it is not easily got hold of. To lift it from the ground, requires more force than would be supposed; for it firmly fixes itself to the earth in an instant, and but a few moments elapse before it is so far down, that its back is level with the surface. It feeds upon insects, principally ants, which it captures by its long extensile tongue; and this appears to be furnished with a glutinous secretion which causes them to adhere to it.

The *ornithorhyncus* (so named from its *bird*-like *bill*), is an animal of such extraordinary aspect, that the specimen first brought to this country, at the end of the last century, was supposed to have been *made up*, by the attachment of the beak and feet of a bird to the body of an otter-like quadruped. It was not until other specimens had arrived, and had been submitted to most careful examination, that naturalists were satisfied of the real existence of such an animal. Since that period, its true place in the scale, depending upon the mode in which it produces and nourishes its young, has been a most fertile source of controversy; but the question may now be regarded as set at rest by the

command of materials and of power of co
would almost certainly fail of solving—so ma

is only after attentively studying the structur
animals, as presented to our view by an all-w
tor, that we become aware of the complex
these conditions, and of the variety of adaptati
sary to fulfil them.

In regard to the place of the class in the ve
series, this is easily determined to be between
tiles and Mammalia. Like the former, its me
oviparous, and like the latter, they possess a
double circulation and warm blood. In orde
the vertebrated animal to its aërial residence,
ously necessary that the body should be of as l
gravity as possible, that is, should be as near

provision also exists in insects; and as the gr
vity of the vital processes depends greatly upo
temperature which this energetic respiration
a provision is required for keeping in this
not allowing it to be carried away by the at
through which the bird is rapidly flying.

The first and third of these objects—the lig
the body and the extension of the respiratory
are beautifully fulfilled in a mode which will
to correspond with the plan adopted for the
pose in insects. The air which enters the b
restricted to a single pair of air-sacs, or lun
near the throat, but is transmitted from the
to a series of large air-cells disposed in the
and in various other parts of the body. Even
rior of the bones is made subservient to the
pose, being hollow and lined with a delicate m

is by very powerful muscles; and there is another
s which pass from the lower part of the spine to
toes, turning over the knee and heel, in such a
ner that the flexion of these joints shall shorten
s: by this contrivance, the simple weight of the
flexes the toes, and birds are thus enabled to sleep
hed on one foot. Most commonly the feet possess
toes, of which one is directed behind and three in
t. This posterior toe opposed to the rest is not,
ever, analogous to the thumb of Quadrumana, which
ly represented in birds by the spurs of the Fowl
c. In some birds two of the toes are disposed behind,
two in front; in others the posterior toe is deficient;
thers, again, it is brought forwards. The number
ints in the posterior toe is but two; in the external
five.

he upper part of the skeleton of the trunk is pecu-
y adapted to give power to the wings. The *sternum*
breastbone is made to project forwards with an
ated ridge or keel, to which the strong muscles
h depress the wings are attached; and from the
th of this, the powers of flight may be in some de-
judged of: in the ostrich tribe, where the wings
not sufficiently developed to raise the bird off the
nd, it is quite flat. The shoulder-bones are con-
ted with the sternum and with each other in a much
nger manner than in other vertebrata. The two
vicles, or collar-bones, are united together on the
tral line, forming the *furcula*, or merry-thought;
the use of this is to keep the shoulders apart, not-
standing the opposing forces exerted by the action

Sternal apparatus of the Common Harrier:
a, furcula; *b*, keel of sternum.

lying. It is generally firm, and its angle open, in
portion to the power of flight. Besides this, we find
sternum connected with the shoulder by two bones
med *coracoid*, which in man and the other Mammalia
scarcely developed, being merely short processes from
shoulder-blade, which do not reach the sternum.
n order to give as great firmness as possible to the
tres of motion of the wings, the trunk of birds has
little flexibility; the vertebræ being firmly jointed
one another, and the ribs united to the sternum by
y prolongations of the latter, instead of by cartilages.
t this want of flexibility of the trunk is counter-
anced by the length and flexibility of the neck. The
nber of cervical vertebræ (which in the longest-
ked Mammalia is never more than seven) is very
siderable, varying from twelve to twenty-three,
highest number being present in the Swan tribe.
se are so jointed together that the head can be
ned completely round (the position assumed when
rest) or moved in any direction. The jaws or man-
les of birds are not furnished with teeth; but are
ered, like those of the Chelonia, with a horny enve-
e, which sometimes projects considerably beyond
m, and forms the *bill*. This is occasionally furnished
h little projections, which in some degree supply the
ce of teeth; but it is only in the birds of prey that
ese are supported by any corresponding projections
the bone beneath.

or on soft herbage, its muscles are reduced to extreme tenuity, so that it is scarcely distinguishable from the proventriculus. The dilatation of the craw is sometimes wanting. In parrots and pigeons it is an important organ in the nutrition of the young. It is furnished with numerous glands, which become developed in both sexes during the period that they alternately perform the duty of incubation; the function of these is to secrete a milky substance, with which a part of the food swallowed by the parent is impregnated, and this is then disgorged for the supply of the young.

The development of the senses of birds varies in different tribes according to the mode in which they are adapted to obtain their prey. The sight is almost always extremely acute, and is the chief means of seeking food. The powers of vision in the rapacious birds are probably the greatest. A hawk has been known to distinguish a lark, coloured like the clod of earth upon which it is sitting, at twenty times the distance at which it would be perceived either by a dog or man. The rapacious birds seem more remarkable, however, for their *length* of sight; those which, like the swallow, capture insect prey on the wing, must have a *quickness* of sight of which we can scarcely form a conception, since, while flying at the rate of three miles in a minute, they are constantly on the watch for their victims. The sense of smell does not seem to be in general highly developed in birds; even the vultures would seem to become cognisant of their food at least as much by sight as by scent. The sense of hearing seems to be in general tolerably acute, especially in the nocturnal birds of prey, some of which possess—what the rest want—an external cartilaginous ear. The tongue of birds does not appear to serve as an organ of taste, except in a few species. It is employed in various ways as a means of obtaining food. The sense of touch appears to be generally very obtuse; but in such as the duck, which search for their food in mud, where neither sight nor smell can be of much avail, the bill is covered with a skin abundantly supplied with nerves of sensation, in order that the animal may feel about for its hidden sustenance.

Of all the endowments of this [illegible]

direction of these, the place for their nests be selected; their materials collected; the selves built, and the young reared in them tions are performed; and many curious are employed to obtain food. These it is to indicate in general terms; since it is that the habits of birds have something each species, yet that in all the individu species they are as precisely alike as the stances will admit. Nevertheless, there in birds a degree and kind of adaptation conditions, which insects do not possess, display an amount of *intelligence* superior found in that class. And in the domesticabl tribes of birds, we see an obvious appro that higher form of attachment to man, wh bited by many species among Mammalia.

There is a more striking conformity in class of birds to one general type, than is pr in any other group of equal extent in the wh kingdom. The instances of any remarkable from it are very few; the chief is that exhib Ostrich tribe, in which the development of t very small. In no other instance are eit extremities wanting; and thus birds never irregularity occasionally presented by fish and even Mammalia.

Owing to this general conformity of type, vision of the class is a matter of some diffi it is not easy to say what characters should b as of most importance, and what are but And this difficulty extends also to the smal sions; in separating which, characters that trivial are often necessarily employed from others. The following orders may probably as constituting groups of species having a semblance to each other, and a well-marked larity from the rest.

The NATATORES, or Swimming-Birds, hav the union of the toes w[illegible] a web, so that the which the foot a[illegible] the water is greatl The legs are [illegible] placed behind, t[illegible]

ction common to many of them, and particularly rvable in our ordinary poultry. The character of order is chiefly derived from the structure of the which are furnished with three toes, united at their by a short membrane, and with one behind, higher the rest; and these are armed with short, blunt, robust nails, for the purpose of scratching up their

the first of these orders, the habitation is, more ess exclusively, aquatic; in the second, marshy es are chiefly frequented; and the third and fourth ain birds essentially adapted to live on the ground, to seek their food without rising into the air. In remaining orders, the habitation is more or less al.

he Scansores, or Climbers, pass most of their time rees, clinging to the branches by means of their which are specially adapted to that purpose. The rnal toe is turned backwards, as well as that which posterior in the Rasores, so that they have two in front and two behind. This conformation pre- s them from walking readily on the ground; and, r powers of flight not being usually great, they are so active as the Insessores.

he Raptores, or Birds of Prey, constitute a group ciently well marked by the robustness and muscu- y of the whole body, the strength of the legs, and ie bill and talons. The former is strong, curved, p-edged, and sharp-pointed; and all of the toes— e before and one behind—are armed with long, ag, and crooked claws.

here now remains a very extensive group of birds, enting no very marked differences amongst its ibers, and not readily defined by any striking cha- ers which separate it from the rest. Accordingly, usually made to constitute but one order, that of ssores, or Perching-Birds. The principal character hich all these agree, is the slenderness and short- of the legs; the feet have three toes in front and behind, and the two outer ones are united by a short membrane; they are all slender, flexible, moderately long, with long and slightly curved claws. se feet are readily distinguishable from those of the er orders: they are destitute of the webbed expan- possessed by the Natatores; they have not the at strength and destructive talons which charac- e the Birds of Prey; nor do they present the very nded toes which enable the Waders to walk safely r marshy soils, and tread lightly on the floating es of aquatic plants. They are adapted to enable bird to *rest* on the branches of trees, but not to to them; and, accordingly, the birds of this order a large proportion of their time on the wing.

f all these orders, the Cursores present the nearest oach to the Mammalia in their conformation and e of life; but it is among the Insessores that we most developed those characters which have been tioned as distinguishing the class—power of flight, ty of plumage, and melody of voice. These, there- as the types of the class, will be first considered.

Order I.—Insessores.

his order, composed of the Perching-Birds, is the t numerous and varied of the whole class. Its acter seems principally negative; for it embraces e birds which are neither swimmers, waders, bers, rapacious, or gallinaceous. Nevertheless, by paring the different tribes it includes, a great gene- resemblance of structure becomes apparent; and insensible gradations are perceived between those at first appeared most unlike, that it is difficult to blish the subdivisions of the group. The foot, as name denotes, is especially formed for grasping or hing—a peculiarity evinced by the situation of the er toe, which is invariably placed on the same level lane as those in front. The length of the tarsus or k (that which appears the lowest division of the but is really the higher part of the foot) is moderate, often very short in comparison to what is seen in other orders; and, as these birds never seize their prey by their claws, these weapons are never retractile. The perchers are thus distinguished from the birds of prey properly so called; from the climbers they are separated by having three toes directed forwards; whilst the situation of the hind toe enables them to be readily known as neither gallinaceous, wading, nor swimming birds. Their food is various, but in general mixed, consisting of insects, fruit, and grain; those in which the beak is stout and strong feed more upon grain, some of them, however, even pursuing other birds; and those which have a very slender bill feed on insects, or on the juices of flowers. The proportional length of the wings and their powers of flight, are as various as their habits. In general the females are smaller and less brilliant in their plumage than the male; they always live in pairs, build in trees, and display the greatest art in the construction of their nests. The young come forth from the egg in a blind and naked state, and are wholly dependent for subsistence, during a certain period, upon parental care.

The *larynx*, or organ of voice, is always of complex structure in the members of this order, which contains all that are commonly known as singing-birds. There are few that do not either sing, or utter some peculiar note or chatter analogous to song, during the season of courtship; and even of those which in general utter only monotonous cries, or of which the notes are harsh, some are frequently capable of being taught to speak, to whistle airs, or to imitate other sounds.

The families composing this order may be distributed under four large groups or assemblages, characterised by the respective forms of their bills. The Conirostres have a stout beak, more or less conical, and with regular edges. The Dentirostres have the upper mandible notched, as in the Raptores, towards the point; but this notch only exists in the horny covering, and not in the bone. The Fissirostres have a short, broad, horizontally-depressed beak, so formed that the gape of the mouth is extremely wide; it is slightly hooked, but without any tooth at the edge. The Tenuirostres have the bill very slender and elongated; it is sometimes straight, and sometimes curved.

I. Conirostres.—The Conirostres are to be regarded as containing the types of the order, the species belonging to it having the most varied faculties. They feed indiscriminately upon insects and vegetables, and are therefore termed omnivorous. Their feet are so constructed that they can walk upon the ground with nearly the same facility as they perch upon branches. The families included in this tribe are the Corvidæ, or Crows; Sturnidæ, or Starlings; Fringillidæ, Finches; Buceridæ, Hornbills; and Loxiadæ, Crossbills.

Of the family Corvidæ, the common *Crows* are the most characteristic examples, and may be regarded as combining the general characters of the class in a greater degree than any other birds. In every climate habitable by man these birds are found; they are constructed for powerful and continued flight, as well as for walking firmly upon the earth; they feed indiscriminately on animals or vegetables, and, when pressed by hunger, do not refuse carrion: their smell is remarkably acute. They are bold but wary, live in common societies, and possess great courage; when domesticated, they possess a power of imitating the human voice nearly equal to that of the parrot; and, like it, show signs of greater intelligence than is found in the rest of the class. Under the general term *Crow* are included the raven, which is the largest of European perching-birds, and which is bold enough occasionally to carry off poultry; the corby crow, which is very destructive to eggs and young game; the rook, which chiefly feeds on insects, and especially devours the grubs of the Coleoptera, though it occasionally eats grain if its proper food be scarce; the hooded crow, which feeds upon molluscs, &c., on the sea-shore; and the jackdaw, which is a very vigilant enemy of predatory birds. The *magpies* are nearly allied to the crows; as are also the *jays*, which live principally, however, in woods, and feed on

acorns, &c. The STURNIDÆ are best known by the European *starling;* the family seems like a smaller race of crows, which they greatly resemble in manners and structure, but are much weaker.

The FRINGILLIDÆ, or *Finches*, are the smallest of this group of perching-birds, and are readily known by the shortness and strength of their conical bills. They subsist generally on grain. The number of species is very great; and some among them are every where diffused. The sparrows, chaffinches, linnets, goldfinches, bullfinches, and larks, are the kinds best known in this country.

The BUCERIDÆ, or *Hornbills*, are readily distinguished at first sight by the enormous size of their bills, which are swollen or enlarged at the base into protuberances resembling horns or knobs, which are sometimes as large as the beak itself. The form of this excrescence varies much with age; and in very young individuals there is no trace of it perceptible. It is not solid, except in one species, but composed of a fragile network of bony fibres. The use of this curious appendage is unknown. The Hornbills are gregarious noisy birds, of large size, and are peculiar to the Old World. They subsist on all sorts of food, devouring tender fruits, chasing mice, small birds, and reptiles, without disdaining carrion; and they breed in the hollows of lofty trees.

The family of LOXIADÆ, or *Crossbill* tribe, contains a large number of genera, of which the common crossbill can scarcely be regarded as a characteristic illustration, the peculiarity from which it takes its name not being possessed by more than a few other species. This peculiarity consists in the strong curvature of the mandibles, so that their tips pass each other, and not always on the same side; by this extraordinary bill the bird is enabled to extract the seeds from pine-cones with astonishing facility, and it is confined to localities in which these are to be obtained. The species common in Western Europe has of late years become more abundant than formerly in the British Isles, where it was previously chiefly known as an occasional straggler.

Bill of Crossbill: *a* and *b*, muscles which move it.

II. DENTIROSTRES.—This group is the most allied of all the Insessores to the Birds of Prey. As its name imports, the species it includes are distinguished by a distinctly notched bill, and they are the greatest destroyers of insects among the Perchers. With very few exceptions, they either live entirely on insects, or resort to fruit only when insufficiently supplied with their favourite nourishment. The mouth is protected on each side by bristles, which defend the soft parts during the struggles of the prey; and the feet are generally adapted more for perching than for walking. The form of the beak varies in different species; in the shrikes, for example, it is stout and compressed, whilst it is flattened or depressed in the fly-catchers, which lead towards the Swallow tribe. This group includes the following families:—LANIADÆ, or Shrikes, which most prominently manifest the peculiarities of the group. MERULIDÆ, or Thrushes, in which there is less restriction to peculiar kinds of food. SYLVIADÆ, or Warblers, chiefly peculiar for the small size, delicate structure, and vocal powers, of the species it contains. AMPELIDÆ, or Chatterers, distinguished by the enormous width of their gape. MUSCICAPIDÆ, or Fly-Catchers, which are more exclusively confined to insects than the rest of the tribe, and have small and weak legs.

The analogy between the LANIADÆ, or *Shrike* tribe, and the rapacious birds, is extremely evident. In the *most characteristic* specimens of the family, the bill, *which is in all short* and strong, is abruptly hooked at the end, and the notch so deep as to form a small tooth more or less prominent on each side; by this conformation the bird is enabled to take a firm grasp of its food, and to tear it in pieces. The claws, also, are usually strong and sharp. Like many of the the shrikes will sit for hours watching for thei which consists of small birds, and, in the less p species, of insects; and will suddenly dart do such as come within their reach, seize it with th and carry it home to be devoured at leisure. T only pursue small birds, but successfully defen selves against larger ones, even attacking th they intrude in the vicinity of their nests. Many feed also upon frogs and other small terrestrial a This family contains a large number of speci tributed through all quarters of the globe. To the same general structure and habits, differi in subordinate particulars. Some, which are s in powers of flight, pursue insects on the wing; subsist entirely on soft caterpillars, which they for among the foliage of high trees; and others about among bushes and underwood, preying a sects and young or sickly birds, and in the l season destroying great quantities of eggs.

Bill of Shrike.

The MERULIDÆ, or *Thrushes*, have an arch narrow beak, but the point is not hooked, a lateral tooth is not so marked as in the shrikes. theless, the transition from one form to the o very gradual. This family is inferior to the s therefore, in the peculiar organisation adapted pacious habits, but they possess a greater var powers. It is in this family that we find the bird distinguished for the sweetness, compass, and v lity of their song. They are not confined to food, but live much on fruits and berries.

Of this family the common *thrush* (mavis or thrush), the *blackbird*, and *fieldfare*, are well and also characteristic examples. These, as w the *missel-thrush*, *redwing*, *ring-thrush*, &c., are allied species of the same genus, of which the species are distributed over the whole globe. *mocking-birds*, on the other hand, which probably unrivalled for their powers of voice, are restri America: some of them approximate to the shr their habits. A few species of this family have what aquatic habits.

The chief peculiarity which runs through the rous family of SYLVIADÆ, or *Warblers*, is the very size and delicate structure of the species which co it. Excepting the Humming-Birds, we find among elegant little creatures the smallest birds in ex The diminutive golden crests, the nightingale, the throat, and the wood-wren, are examples of this well known to the British naturalist; as are al robins, stone-chats, wagtails, tit-larks, and tit-mi different groups are spread over all the habita gions of the globe, and appear to have a peculia tion in the economy of nature, being specially de to keep down the multiplication of the innum minute insects which lurk within the buds, the or the flowers of plants. The small size of these causes them to escape the notice of the thrush the larger insectivorous birds; whilst their habi vent them from being seized by the swallow an as capture insects only on the wing. The Sylvia for the most part migratory birds; appearing in when the insect world is called into life and acti the renewal of vegetation, and disappearing autumn, when their services are no longer re and when their supply of food diminishes or ce together.

' the family of AMPELIDÆ, or *Chatterers*, the most acteristic examples belong to tropical America, and one is found in Europe—the *wax-wing*. The birds iis family are distinguished from all the other Den-ıtres by the enormous width of their gape, which ıany extends beyond the eye, and in some is nearly ide as in the goatsucker. This bill is not defended ıristles, however, at its corners; and the absence ıese indicates that its wide opening is *not* for the pose of catching insects on the wing, as in the swal- tribe. The chatterers live almost entirely on soft ies and small fruits, which they swallow whole; and food naturally requires a very wide passage. They perpetually hopping among fruit-bearing trees, and eely ever come to the ground. The species which be regarded as the types of this family are very e known, being inhabitants of the deepest and most luded forests of tropical America. They are oftener rd than seen; their notes being peculiarly loud, and red morning and evening from the deepest recesses the forests. Many of them are clothed in a very a and brilliant plumage, which rivals that of the ming-birds.

The MUSCICAPIDÆ, or *Fly-catchers*, are a family hardly numerous than that of the warblers; and are com-ed, like that group, entirely of small birds. This fa-y is more purely insectivorous than any other of the er, few of the species belonging to it ever partaking fruits. These birds have a bill flattened at its base; the sides of the mouth are defended with stiff stles, to confine the struggles of their prey. The mbers of this family are distributed through the perate and tropical portions of the Old World, and temperate parts of the New. Between the tropics, ever, they are replaced in America by the tyrant-kes and fly-catching warblers, both which groups unknown in Africa and India. The *fly-catchers* of ope are small birds, about the size of a sparrow. species is common in Britain, usually arriving it May. It has been observed to take its station he top of a stake or post, from whence it springs n on its prey, catching a fly in the air, and hardly touching the ground, but returning to the same d for many times together.

I. FISSIROSTRES.—The group of Insessores thus desig-d is a comparatively small one; but it is very dis- from all others in the beak, which is short, broad, zontally depressed, slightly hooked, and very deeply , so that the opening of the mouth is extremely . The birds possessing this kind of bill are adapted apturing insects on the wing, receiving their prey all flight into their mouths, which remain open for purpose; and the victim is secured by a gluey lation within, and a strong fence of bristles on the ide, which also serves to protect the soft parts of the from its struggles. Although such is the typical haracteristic form of the bill in this group, it is not ays seen. In some species the bill is stronger and er; and these also are distinguished by having the rnal toe nearly as long as the middle one, and at-ed to it until nearly its end; to these the name *yndactyli* was given by Cuvier, who associated them a separate group. The Fissirostres as a whole are uliarly distinguished by having the powers of flight eloped to the highest degree. All the energies of ir nature seem concentrated in this one perfection; their feet are always very short and weak, and ve but for little else than to rest the body after flight. y may be separated into diurnal and nocturnal, like birds of prey.

his group may be divided into the five following ilies:—HIRUNDINIDÆ, or Swallow tribe; CAPRIMUL-Æ, or Goatsuckers—both these present, in a remark-degree, the organisation which has been described haracteristic of the order; the remaining families e a longer and narrower bill, and are syndactylous—ROPIDÆ, or Bee-eaters; HALCYONIDÆ, or King-fish-; TODIDÆ, or Todies.

he HIRUNDINIDÆ, containing the swifts and swallows, are diurnal birds, remarkable, like the diurnal Raptores, for their close plumage, the extreme length of their wings, and the rapidity of their flight. The *swifts* possess these characters in the highest degree, and surpass all other birds in the power of sustaining a rapid flight for a long time. They are distinguished from the swallows by having the hind toe directed very much forwards; and all four toes are armed with strong crooked claws, which give to the bird such a firm grasp, that it can sustain itself by the side of perpendicular rocks or buildings with great facility. In some species, the tail feathers are very stiff, as in the woodpeckers, and serve as an additional support. They spend their time almost entirely in the air, and pursue insects in flocks, sometimes at a great height, uttering discordant screams. They nestle in the holes of walls and rocks. The *swallows* are less capable of sustaining a continued flight than the swifts, as is shown by their weariness after or during migration, on which occasions they have been seen to alight flat upon the sea. Several species exist in Europe, and many more in other parts of the world. Among them may be mentioned a small species inhabiting the Indian archipelago, which forms its nest of a species of sea-weed, which it macerates in its stomach and then arranges in layers. These *edible birds' nests*, as they are commonly termed, are highly prized as delicacies in China, and constitute an important article of traffic with that country.

The CAPRIMULGIDÆ, or *Goat-suckers*, are nocturnal birds, and have the same light soft plumage which characterises the owls. Their eyes are large, and their gape still wider than that of the swallows, so as to be capable of engulfing the largest insects. They come forth in the twilight and return to rest before morning; but in their other habits they much resemble the swifts, with which, indeed, they are closely connected by intervening species; for, whilst there are goat-suckers which fly by day, skimming over the surface of ponds in small flocks, precisely in the manner of swallows, there is also a swift which only flies at night.

The family of MEROPIDÆ, or *Bee-eaters*, is confined to the warm regions of the Old World; only one species being known as having occasionally strayed to Britain. They have long and pointed wings and short feet, and fly in the manner of swallows. The European Bee-eater annually visits Italy, in flocks of twenty or thirty, and may be seen skimming over the vineyards and olive-plantations, especially pursuing bees and wasps. It is remarkable that they are never stung by these; they seize the insect, and at once crush it by the snap of their powerfully compressive beak.

The HALCYONIDÆ, or *King-fishers*, are remarkable for the great length of the bill, and the extreme shortness of the feet. Their habits are sedentary, much resembling those of the fly-catchers; but their food is more various. The common British species partly lives on small fish, which it takes by precipitating itself into the water, either from the branch on which it had perched, or by suddenly arresting itself during rapid flight, poising for an instant, and then plunging. It returns to its perch to gulp its prey, first killing it by repeatedly beating it against a bough. The TODIDÆ, or *Todies*, are small American birds, resembling the king-fishers in their general form, and may be regarded as representing them in the New World.

IV. TENUIROSTRES.—This group, it has been well remarked, "is among the most interesting of the animal world. Deriving their subsistence, for the most part, from the nectar of flowers, we never fail to associate them in our idea with that more beautiful and perfect part of the vegetable creation, with which, in their delicacy and fragility of form, their variety and brilliancy of hues, not less than by their extracting their nourishment from vegetable juices, they appear to have so many relations." This tribe is confined exclusively to the torrid zone and southern hemisphere. The length and slenderness of the bill are its distinguishing characteristics. It is not by this, however, but by the long filamentous tongue, that the juices of flowers are sucked

up; and to protect this important organ, the peculiar conformation of the bill seems chiefly intended. The tongue is often simply forked; but is sometimes divided into so many slender filaments, as to resemble a painter's brush. The feet are very short and delicate. All these characters are presented in the greatest perfection by the TROCHILIDÆ, or Humming-birds, which are the types of the group. In the CINNYRIDÆ, or Sun-birds, the feet are more lengthened. The PROMEROPIDÆ, or Hoopoes, have the tongue short. The PARADISIDÆ, or Birds of Paradise, are separated by the strength of the feet. And the MELIPHAGIDÆ, or Honey-suckers, have the bill notched.

The TROCHILIDÆ, or *Humming-Bird* tribe, so celebrated for the metallic lustre of their plumage, and particularly for the gem-like brilliancy of some of their feathers, have, within their long slender beak, a tongue capable of protrusion like that of the woodpeckers, and divided almost to the base into two filaments. These filaments are *not* tubular, as they are sometimes described, but are flattened. It is not improbable that the tongue may serve for catching insects, as well as for sucking the juices of flowers; since it is unquestionable that, like others of the order, the humming-birds are partly insectivorous. When hovering over flowers, these birds balance themselves in the air by a rapid motion of the wings, like many flies; and it is by this movement that the *humming* sound is produced, from which they take their name. The flight of these birds, the smallest of the order, is so rapid as frequently to elude the eye. They live solitarily; defend their nests with courage, attacking with their needle-like bills the eyes of intruders, which makes these minute creatures truly formidable; and fight with each other desperately.

This family is exclusively confined to America; and, with few exceptions, to the southern part of that continent and the adjacent West Indian islands. More than one hundred and seventy species are at present known; and others are constantly being discovered. The smallest of them, when plucked, are less than a large humble-bee; and one only, which is much larger than any others as yet known, nearly equals the common swift in size. This bird is also one of the dullest coloured, and its general resemblance to the swifts is very manifest.

The CINNYRIDÆ, or *Sun-Birds*, represent the humming-birds in the eastern continent. They are closely allied to the Trochilidæ in general structure and in the mode of obtaining their food, but their tongue is not so deeply divided. They are small birds, and the males have the most brilliant colours, rivalling those of the humming-birds, during the breeding season; but the garb of the female, and of the male at other times of the year, is much more dull. The PROMEROPIDÆ, or *Hoopoes*, are also restricted to the Old World; one species, the common hoopoe, annually visits Europe, in company with the bee-eaters and other swallow-like birds.

The PARADISIDÆ are among the largest of the Tenuirostres, and seem to live, like the rest of the order, chiefly upon soft vegetable substances. They are confined to New Guinea and the neighbouring islands, and for a long time no specimens were obtained but such as had been deprived by the natives of their legs, whence it was at one time supposed that they were destitute of limbs, and supported themselves entirely upon their airy plumes. The extraordinary development of their feathery appendages is well known; but of the purpose these serve in their economy, no plausible account has been given. The very restricted locality of these birds, and the savageness of the people who inhabit it, have prevented naturalists from obtaining much knowledge of their habits. They are partly supported upon insects.

The MELIPHAGIDÆ, or *Honey-Suckers*, are distinguished *from all the preceding families by their notched bill; their tongue is* terminated by a bunch of delicate filaments, *and the hind toe is so strong and robust, that it serves as a support to the bird during the process of* feeding. This group is chiefly confined to Australia, where its members abound in great variety of form, and where they find a never-failing support in the luxuriant vegetation of that country.

The members of the family CERTHIADÆ, which consists of the Tree-creepers, Nuthatches, &c., strongly resemble the scansorial birds in their habits, but they more closely approximate to the Tenuirostres, and especially the Meliphagidæ, in general structure. Like those, they are of small size; the foot has three of the toes directed forwards, and the bill is more slender and delicate than that of the woodpeckers. The *Tree-creepers* bore into trees, however, and rest upon the tail in climbing, much as do the woodpeckers, but they rather seek for their food in the natural chinks of the trees, or among the mosses and lichens which cover the branches. The *Nuthatches* have a stronger bill, which is straight and pointed, like that of the woodpeckers. They use it, however, rather to scale off the bark than to perforate it, and they do not support themselves upon the tail. They feed not only upon insects but upon various seeds, and are celebrated for the instinct of fixing a nut in a chink while they pierce it with the bill, swinging the whole body as upon a pivot, to give effect to each stroke. The British species is about the size of a robin, its note loud, and its disposition remarkably fearless.

Order II.—Raptores.

The rapacious birds constitute a well-marked group, which may be compared with that of the Carnivora among Mammalia. In comparison with the Insessores, their number is but few; for had it been otherwise they would soon have extirpated the whole race. They usually breed but slowly, leading solitary lives, and never appearing in numerous collections. Most of them are large and powerful birds; and, what is an exception to the general rule, the female is larger than the male, but her plumage is usually of a duller aspect. There are few of this family which do not show great strength of wing; but the power and swiftness of flight that are possessed by the different species, vary with their habits. As among the carnivorous Mammalia, we find some species adapted to pursue and bring down living prey; and these are endowed with the greatest activity and strength of movement. Others feed upon the carcasses of animals that have met their death in various ways, in search of which they have to perform long journeys: these are endowed with great power of wing, but their swiftness is less. The least degree of these faculties among the raptorial birds, exists in those which feed upon decomposing animal matter, or which hunt after such small game as it requires neither swiftness nor power to seize.

Rapacious birds are all remarkable for their strong hooked bill and large acute talons. The force of these is indicated by the size of the muscles of the legs and thighs; and the foot is usually but of moderate length, that its power may not be lost by being diffused over too large a space. It is by the talons that the prey is usually struck first; and, when secured by the feet, it is torn open by the bill. For this purpose there exists in the typical Raptores a strong and sharp tooth-like projection from one or both of the mandibles, which is of material assistance; but in such tribes as feed on carrion or small animals, it is nearly or entirely deficient.

This order is usually divided into two series—the *diurnal* and *nocturnal* Birds of Prey; the former containing the falcons, eagles, vultures, &c., and the latter the owls. As the falcons, vultures, and owls, however, constitute three distinct families of equal rank, it will be preferable thus to consider them. They are chiefly distinguished from each other by the presence or absence of the tooth on the bill, already adverted to; by the degree in which the neck is clothed with feathers or destitute of them; by the size of the eyes, and the presence or absence of a fringe of feathers around them, and other minute characters the relations of which

eculiarities of the several families will be

probably has for its object to prevent the
of light from the sides, above, or below,

and to enable them to concentrate their whole power of sight upon the object directly before them—as when we look through the hand contracted into a tube at some object which we desire to see more distinctly. This fringe is most remarkable in the *Barn Owl* and its *allies*. In the owls which are partly diurnal in their

Barn Owl.

habits, this circular fringe is hardly perceptible. The owls seek their prey, not by power of flight, but by stealing upon it unawares; hence the movement of their wings should be as noiseless as possible; and this object is peculiarly answered by the downy character of the whole plumage, and by a particular arrangement of the barbs of the feathers at the edge of the wings. The external toe, as in the osprey, can be directed backwards as well as forwards. Their period of activity being twilight, or during moonlight nights, that of their repose is during the day; and, if then disturbed, they make the most ludicrous gestures, which seem principally intended, however, to enable them to get a clear view of the object which annoys them. Owls are feared by all smaller birds, which do not hesitate, however, to attack them during the day. Their food is wholly animal; consisting of mice, frogs, and other small terrestrial vertebrata, small birds, fish in some instances, and insects.

Order III.—Scansores.

The peculiar disposition of the toes in the birds of this order, two being placed behind, and all four arising nearly on the same level, gives them great facility in climbing the branches of trees, but proportionally impedes their progression on level ground. By this character they may be readily distinguished from all other birds, notwithstanding many and striking variations in the form of the bill and wings. The nests of this order are generally less skilfully constructed than those of the Insessores; and the birds often employ for this purpose the hollows in decayed trees: one family is remarkable for depositing its eggs in the nests of other birds. Their flight is ordinarily but moderate. Their nourishment consists of insects and fruits; and the species feeding upon each may be distinguished by the greater or less robustness of the beak. This order may be divided into the four following families:—1. PICIDÆ, or *Woodpeckers*, which may be regarded as the types of the order, presenting its peculiar characters in the highest degree. 2. CUCULIDÆ, or *Cuckoos*. 3. RAM-

RHAMPHASTIDÆ, or *Toucans*. 4. PSITTACIDÆ, or *Parrots*. This last family is separated from the rest by so many peculiarities, as almost to constitute a distinct order.

1. The PICIDÆ are chiefly characterised by their long, straight, angular bill, the end of which is compressed into a wedge, adapted to perforate the bark of trees. The tongue is also of peculiar conformation, being worm-like in its shape, barbed at its point, and capable of being suddenly thrown out to a great length. By this mechanism the bird can introduce it into holes and crevices, or even under the loose bark of trees infected by those peculiar insects which it is its province to destroy; and these they obtain, not only by transfixing them with the barbed point, but by causing them to adhere to it by means of a viscid glue with which it is covered. The feet of these birds are short but very strong; the nails are broad and crooked. As an additional and powerful support in their rapid and perpendicular ascent up the trunks of trees, their tail-feathers are very firm, and terminate in points; so that this member, being pressed against the bark, is of assistance to the bird in maintaining its perpendicular attitude. The species of this family are extremely numerous, and are generally distributed over the globe, with the exception of Australia.

2. The CUCULIDÆ, or *Cuckoo* tribe, are a numerous and diversified race, spread over all the temperate regions of the globe. They are principally distinguished by the short and slender make of the feet, of which one of the back toes can be occasionally brought forwards. The beak is of mean length, slightly arched, and compressed at its sides. Most of this family are migratory, and scarcely any build nests of their own. They fly rapidly, and subsist upon insects and fruits. The common cuckoo has long been celebrated for its habit of depositing its eggs in the nests of other birds, generally insectivorous species; and, what is more extraordinary, the foster parents, often of species inferior in size, bestow as much care upon the young cuckoo as upon their own proper nestlings, even though the rearing of this involves the destruction of their own young. For, if other eggs are hatched with that of the young cuckoo, the latter speedily ejects the rightful tenants from the nest, and receives all the attention of their parents. If it were not for this, it must speedily perish for want, from the frequency and urgency of its demands for food, and its incapability of assisting itself, up to an advanced age. The cuckoo feeds principally on caterpillars, and also devours cherries and the smaller fruits; it is sometimes seen to pursue insects on the wing. It is an unsocial bird, seldom congregating with its species, except at the time of migration.

3. The RAMPHASTIDÆ, or *Toucan* tribe, are easily recognised by the enormous size of the bill, which is nearly as large and long as the body itself, but internally very light and cellular; its edges are toothed, and both mandibles are arched towards the tip. The tongue is narrow and elongated, and laterally barbed like a feather. Their feet are formed more for grasping than climbing; accordingly, they always live among trees, and proceed by hopping from branch to branch. So light and elegant are their movements, that in the living bird, in its natural situation, the disproportionateness of the bill does not attract observation. Its large size is to give a more extensive distribution to the nerves of smell, for the purpose of enabling the birds to discover their food, which consists chiefly of the eggs and young of other birds, and also to enable them to obtain it, by dipping it into the deep hanging nests which abound in their natural abodes, for which purpose its surface is endowed with considerable sensibility, enabling it to feel the contents of these nests. The size of the bill prevents their swallowing their food in the usual manner, and they accordingly throw it into the air and catch it in the throat as it descends, a habit practised by many other birds also, in which the tongue is unusually short, or of a form unfit to assist in swallowing. Toucans are mostly large-sized birds, and clothed with brilliant plumage. They are peculiar to the warm regions of America, where they live in small flock rent species often associating together. They n the trunks of trees.

4. The PSITTACIDÆ, or *Parrots*, constitute a which is very widely diffused through the torr in both new and old continents, and is scarcel beyond it. It contains a large number of speci of which has its peculiar locality, the short w these birds not enabling them to traverse larg of sea. They correspond with the other Scans little else than the structure of the foot, and formed rather for grasping than for climbing. I used for conveying food to the mouth, a peculia where else seen but in the goat-suckers. Their stout, hard, and solid, curved and pointed ver as in the diurnal birds of prey, which they may be regarded as connecting with this order. Th sist, however, upon vegetable food at all ages, an a peculiar provision for supplying their young, gous to that which will be described as posse the pigeons. Their jaws are set in motion by a variety of muscles than are found in other birds. tongue is thick, fleshy, and rounded; and their or organ of voice, is more complicated than in birds—by which peculiarities they gain their fac imitating the human voice as well as other Their voice, in a state of nature, however, is lo harsh. They use their crooked bills in clam upon trees, and nestle in hollow trunks. They upon the succulent parts of vegetables, especiall and fruits. They are distinguished from the rest scansorial birds by their intelligence and docility, ties in which some species are unsurpassed members of the class.

Order IV.—Rasores.

This order, corresponding with the *Gallina* poultry tribes, consists of birds with bulky bodi essentially formed to live upon dry ground. Th the most easily domesticated of the whole class furnish man with a considerable amount of sa and wholesome food, and their fecundity is very The majority of them are at once known by their thick legs, long necks, short wings, and large tails; and the heads of many, especially of the are ornamented with elegant crests. The form bill is well seen in the common cock; the upper ma is vaulted, and, at the same time, destitute of any the whole is short and strong, having a peculiarly appearance. The wings are muscular, but their fe have rounded ends; and the breast-bone pres much smaller surface for the attachment of the m than in the previous orders, so that the power of is comparatively small. Their food, with few tions, is entirely vegetable, and their chief sup derived from the seeds and grains of various Many of them eat also the green portions, and this respect nearly peculiar among birds. Alm of them have a large crop and an extremely mu gizzard.

The Rasores are mostly social birds, and are r domesticable. In general they deposit and hatch eggs on the ground, in a rudely-constructed straw, but some of them, which reside in forests, in trees. Each male usually associates with females; he takes no part in the construction nest or in rearing the young, and these are gen numerous and able to run about and provide for selves the moment they quit the shell. When the case, the male is larger and more gaily co than the female. But in the few species which ciate in pairs, such as the ptarmigan and partrid sexes nearly or quite resemble each other, both and colour.

From the strong resemblance which subsists all the birds of this order, the division of them families is difficult. The following may be re as the most natural distribution of them into gro

1. PHASIANIDÆ, *Pheasant* and *Fowl* tribe, distin

f the shortness of the hind toe, the presence of spurs
n the legs, and the beautiful development of the tail.

Cracidæ, or *Curassow-birds*, a tribe of poultry re-
ricted to America, the legs of which are destitute of
ours, and the hind toe so much developed, as to give
onsiderable power of perching. 3. Tetraonidæ, *Par-
idge* tribe, having a very short hind toe, and also very
ort tails. 4. Columbidæ, the *Pigeon* tribe, which are
uch isolated from the rest, and may be regarded as
some respects allied to the Insessores. From the
ell-known character of most of these birds, the de-
cription of the families need not be detailed.

1. The whole of the Phasianidæ, with the exception
f the turkey, are restricted to the Old World. The
haracters by which they are known from the other
amilies, are those which peculiarly distinguish the
rder; hence there can be no hesitation in regarding
his family as its type. It is in the hotter parts of Asia
hat the most brilliantly coloured birds of this family
resent themselves in the greatest numbers. The *pea-
ock*, for example, abounds in the forests of India; and
he wild specimens even surpass the domestic ones in
rilliancy. The *turkeys* are the only representatives
f this group in the New World, whence they were
rought by the early discoverers, and are now quite
aturalised in Europe. The *guinea-fowl* is originally
native of Africa, where it lives in large flocks, in the
eighbourhood of marshes. Its noisy and querulous
disposition renders it incommodious in poultry-yards,
although its flesh is excellent. Of our common fowls,
he original stock, like that of most domesticated races,
s obscure; but it was probably a species of *gallus*, in-
abiting Java or Sumatra. The *pheasants* were origi-
ally brought from the banks of the Phasis in Asia
Minor; several very handsome species abound in diffe-
ent parts of Asia.

2. The Cracidæ, or *Curassows*, which are restricted
o America, offer a remarkable contrast, in their plain
colours, to the brilliant plumage of the Asiatic races
hich occur in nearly the same parallels of latitude.
hey are equally capable of domestication with the
owls; and their flesh is of excellent quality.

3. The Tetraonidæ, or *Grouse* tribe, also differ strongly
rom the Phasianidæ, in the comparative dullness of
heir plumage, as well as in the extreme shortness of
he tail. The *grouse* are formed to inhabit cold climates,
nd are found in Europe, Asia, and North America.
he largest species, commonly known as the caper-
ailzie, is the largest of the true poultry, surpassing
he turkey in size. It particularly feeds on pine shoots.
hese birds strut with outspread tail, in the manner of
he turkeys; and are polygamous. The *ptarmigan*
ive in pairs, and do not strut in this manner; the more
enerally diffused species become white in winter;
here is one species peculiar to Britain, however—the
oor-fowl or red grouse—which does not change.
Nearly all the grouse have the toes and legs more or
ess covered with soft feathers; a character which dis-
ppears in the *Partridges*, an extensive group, scat-
ered in nearly all parts of the Old World, but unknown
n the New. In the *Quails*, we have the miniature re-
emblance of partridges, but the tail is so short as to
e nearly imperceptible.

4. The family of Columbidæ, containing a large
umber of elegant and lovely birds, appears as much
olated from the rest as the Parrots are from the
cansores. Although it is particularly numerous, and
pread over every part of the world, there is no diffi-
ulty in distinguishing its members from all other birds.
ne of their chief peculiarities is the *double* dilatation
f the crop, which expands on each side of the gullet;
nd the young are fed with grain disgorged from this
eceptacle by the parent, and impregnated with a se-
retion which it forms. These birds live invariably
n pairs; they nestle in trees, or in the holes of rocks,
nd lay but few eggs, though they breed often. This
amily includes the whole of the well-known tribe of
igeons and *Doves*. Some of the tropical species are of
onsiderable size, and of very rich plumage.

The *passenger-pigeon* of North America breeds in such immense numbers, as to darken the air for a considerable period when the flock takes to flight, and to destroy all the herbage where they settle.

Order V.—Cursores.

This order contains a small number of species, differing so considerably from one another, that almost every one may be regarded as belonging to a different family, and yet all agreeing in one characteristic—the non-development of the wings, and the enormous size and power of their legs—by which they seem justly separated from all other orders of birds. They may be regarded as in many respects intermediate between the Rasores and Grallatores; but they also present many remarkable points of approximation to the Mammalia. The most obvious of these are the loss of the powers of flight, and the dependence on the legs alone for locomotion; and the deficiency (most conspicuous in the cassowary) of barbs upon the feathers, so that they much resemble hair. In their internal structure, moreover, similar approximations exist: thus the ostrich has the rudiment both of a diaphragm and urinary bladder, which organs are wanting in other birds, whilst all Mammalia possess them.

Although destitute of the powers of flight, wings exist in an undeveloped or rudimentary state; and it has been observed that, when the ostrich is running, its small anterior members execute analogous motions, which seem to assist it. Their muscles, however, requiring but little strength, the sternum has no prominent keel, but is flat as in man; whilst, on the other hand, the muscles of the posterior extremities are of enormous size and power. Only five genera are at present known to exist in this order; and of one more, which seems now extinct, remains are preserved to us which indicate its existence two centuries since.

The *struthio*, or ostrich, is a well-known bird in the tropical parts of the eastern hemisphere; its feathers do not differ so widely from those of other birds as do those of the cassowary, being furnished with barbs; but these do not adhere to one another, so that no continuous resisting surface is formed. Still the wings present sufficient expanse to assist the bird in running; which movement it executes so swiftly that scarcely any animal can overtake it. The *rhea*, American ostrich, or naudon, is about half the size of the African ostrich, and more thinly covered with feathers. Two species exist, one inhabiting the central parts of South America, where it is as abundant in some localities as the ostrich in Africa; and the other in Patagonia, where it is rare. The naudon is easily tamed when young, and its flesh is eaten: it has been observed to swim with facility.

The *casuarius*, or cassowary, has wings shorter than those of the ostrich, and quite useless in aiding progression. Besides the peculiarity of the feather, which has been already mentioned as giving it the appearance of hair, there is another, consisting in the great development of the *accessory plume*, so that two or even three equal stems appear to grow from the same quill. In its general form and aspect it much resembles the ostrich, but differs in the structure of its digestive organs. The head is surmounted by a bony prominence, covered with horn. The skin of the head and neck is bare of feathers, and of a bright blue and flame colour; it is furnished with wattles, like those of the turkey-cock, which change colour under the same circumstances. It lives on fruit and eggs, but not on grain. It is an inhabitant of the Indian archipelago, and is the largest-bodied of birds, next to the ostrich.

The *dromaius*, or emu, is a native of New Holland, and is closely allied to the cassowary; but its plumage is more depse, from its feathers being more barbed.

The *apteryx* of New Zealand appears, of all birds, to have the wings reduced to the most simple rudiments; and it presents, at the same time, many points of approximation to the Mammalia. It has a complete diaphragm, and no air-cells exist in its abdomen; nor are any of its bones hollow. The bill is long and slender;

the rudiments of wings are terminated by a sharp hook, which seems to be an important organ of defence; the feet have three toes in front, and the rudiment of a fourth behind, the claw of which is alone externally

The Apteryx.

visible. The size of this bird is about that of a domestic fowl, and its colour a deep brown. It runs with rapidity, and defends itself vigorously with its feet. It is nocturnal in its time of action, and subsists on insects. Its native name is *kiwi-kiwi*, derived from its cry.

With this group is probably to be associated the *dodo*, now known to us only by some very imperfect remains, and by the paintings and descriptions of naturalists nearly two centuries since, when it seems to have existed in the islands on the eastern coast of Africa, especially Madagascar; though no traces of it can now be found there.

Order VI.—Grallatores.

The Grallatores, Waders or Stilt-birds, derive their name from their habits and conformation. Their long legs raise up their bodies as it were upon stilts; and, thus elevated, they frequent the banks of rivers and lakes, marshes, the shores of estuaries; and, whilst resting with their feet upon the land, derive their nourishment chiefly from the water—some feeding exclusively upon small fishes, aquatic mollusca, worms, small reptiles, and water insects—whilst others are of more terrestrial habits and food. Such as are more especially aquatic have a short web to their toes. Their wings are long, affording them the power of changing their habitation with the seasons, which most of them enjoy. During flight, they stretch out their long legs behind, to counterbalance their long necks; and the tail is always extremely short, its function as a rudder being transferred to the legs. They mostly construct or choose their nests upon the ground; and the young are enabled to run about as soon as hatched, except in those species which live in pairs. The Waders are remarkable for their power of preserving a motionless position upon one leg for a considerable time.

The Waders may be grouped together under four families, principally characterised by the form of the beak:—1. Ardeidæ, the *Heron* tribe, in which the beak is long, thick, and stout, and has usually cutting edges, as well as a point. 2. Scolopacidæ, the *Snipe* and *Woodcock* tribe, in which the bill is long, slender, and feeble. 3. Rallidæ, the *Rail* and *Coot* tribe, in which the bill is less slender; but the chief character is derived from the extreme length of the toes. 4. The Charadriadæ, or *Plover* tribe, in which the bill is of moderate size, and the back toe either entirely absent, or not long enough to reach the ground.

1. The family of Ardeidæ includes the Cranes and Storks besides the true Herons. By the *Cranes* this order is connected with the last, for nearly all of them are large birds, with short powerless wings; their necks long and frequently naked, and their habits more terrestrial than those of any of their congeners. They feed almost exclusively upon vegetables; and have a muscular gizzard. Most of them live in warm latitudes; and those which frequent Europe migrate southwards in the autumn and return in the spring.

The Herons differ from the cranes in being decidedly carnivorous; they are known by a larger and more pointed bill, and by the greater length of their legs. Their stomach is a large undivided sac, but slightly muscular. As a whole, they are the most beau all the Waders; not so much, however, on acc the colours of their plumage, as from the elegan and prolonged feathers which ornament nearly species. They build in societies, usually in tre neighbourhood of banks of rivers; but genera and live solitarily. They are chiefly supported for which they watch in some concealed situation, fixing them as they pass, with their long and sha The *storks* are less aquatic in their habits than of the family, nestling by preference on tow chimney-stacks; each pair returning to the sa in the spring, after having passed the winter in The common white stork of Europe is held in popular respect, owing to its utility in destroying and other noxious animals; but in England, every one that shows itself is shot, whence the is very uncommon.

2. The Scolopacidæ, or *Snipe* tribe, character their long, slender, and feeble bill, which only them to bore in the mud in search of worms an insects, have all nearly the same conformation, th habits, and the same distribution of colours; an is difficult to distinguish amongst them. They a remarkable for the delicacy of their legs, and th ness of the hinder toe. They run with vast celeri have considerable powers of flight; and they ha the faculty, in part, both of swimming and diving. The females are usually larger than the males, and lay their eggs on the ground, in little or no nest. Their geographic dispersion is as wide as their locomotive powers are great. The shores of every part of the world abound with *sandpipers* and *curlews*; whilst snipes, woodcocks, &c., frequent the inland waters and marshy grounds. The *stilts* surpass all the rest of this family, and probably therefore all other birds, in the length and slenderness of their legs.

Stilt.

3. The Rallidæ, or *Rail* tribe, are furnish very long toes, for traversing aquatic herbs they are even useful in swimming, especially species in which their surface is extended by a of membrane. They are also distinguished by t of the body, which is very thin and narrow—a ture adapted to their habits and mode of life, an live for the most part in the thick and tangled of the reeds and aquatic vegetables which cl sides of rivers and morasses. Their wings ar or of moderate length, and their flight feeble; h run with considerable swiftness. They are for t part solitary and timid birds, hiding themselve least approach of danger, but quitting their semi- retreats morning and evening, to feed in mo spots. The flesh of these birds is delicate; they live chiefly upon aquatic seeds and veget ment, they may be regarded as aquatic Gall By the peculiar form of their bodies, and their of running, they are able to make their way dense masses of reeds and high grass, with a facility, as to escape even after being dea wounded. The females are mostly larger t males, and exceed them also in brightness of co The *rails*, *coots*, and *crakes*, are the chief British of this family, and are sufficiently characteristi

CONDUCTED BY WILLIAM AND ROBERT CHAMBERS, EDITORS OF CHAMBERS'S EDINBURGH JOURNAL, EDUCATIONAL COURSE, &c.

ER 31. NEW AND IMPROVED SERIES. PRICE 1½d.

ZOOLOGY—(CONTINUED.)

the family Rallidæ has been classed a remarkd, the place of which is rather doubtful. This is *ingo*, which is perhaps rather to be considered f the duck tribe, with an inordinately long neck s. The front toes are webbed to their ends, and d toe is extremely short. The mandibles are y bent downwards, about the middle of their and they are roughened at the edges, like those lucks, to which the fleshiness of the tongue also n alliance. They feed on mollusca, insects, the f fishes, &c., which they seize by means of their k, turning the head downwards, to use to advan- crook in the upper mandible. They construct ests in marshy situations, placing themselves of them during the act of incubation, being in- ted by the length of their legs from sitting on the usual manner.

Flamingo.

e CHARADRIADÆ, or *Plover* tribe, are less aquatic ost of the other families. The legs are long, back toe is either quite absent, or so short as each the ground. They live only on sandy and ered shores, or on exposed commons, congre- in flocks, and running with great swiftness. The sually of moderate strength, enabling these birds trate the ground in search of worms, to obtain they have the habit of patting with their feet, causes the worms to rise. The species in which l is more feeble, frequent meadows and newly ed land, where this food can be obtained with ease; those which have stronger bills subsist additionally on grain, herbage, &c. Of the plovers several species exist in Britain; and others are distributed through most other countries. Some chiefly frequent the sea-coast, and others the upland moors. The *Lapwings* are nearly allied to the plovers, and like them are migratory, passing the winter in warm latitudes; they are peculiar to the eastern hemisphere. They are very noisy birds, screaming at every sound they hear, and defending themselves with courage against birds of prey. They derive their name from the stratagem by which they lure away intruders from their nests; they drop their wings in flight, appearing as if wounded, and thus induce their pursuers to follow them to a considerable distance.

Order VII.—Natatores.

The Swimmers are, of all the orders of birds, the most easily recognisable by the structure and position of their oar-like feet. This peculiarity, which occasions that awkwardness of gait on land which every one may observe in ducks and geese, is extremely favourable to those birds whose "business is in the great waters." The body is boat-shaped, and the neck is very long in proportion, for the purpose of reaching prey beneath the water when the bird is floating on the surface. The thick downy covering is rendered impervious to water by the abundant application of the oily secretion. The bones of these birds are not hollow, like those of the rest of the class, but are filled with an oily marrow. In this, and in other points, their structure approximates to that of reptiles. Their circulation is less energetic than that of the other orders, and is capable of being considerably retarded in diving birds, by the obstruction of the respiration, without injury.

As the water is the element on which these birds are formed to move, so does it also supply them with food. Some of them live on aquatic plants and submarine insects, but the greater proportion prey upon fish and those innumerable swimming and creeping things which subsist in the sea and cover its shores. In general, several females associate with one male, and the young are hatched in a condition which renders the co-operation of both parents for their support unnecessary, being able to take to the water and swim about in search of food, the instant they are liberated from the egg-coverings.

This order may be divided into five families—1. The ANATIDÆ, or *Duck* tribe; 2. The LARIDÆ, or *Gulls*; 3. The PELICANIDÆ, or *Pelicans*; 4. The COLYMBIDÆ, or *Divers*; 5. The ALCIDÆ, or *Penguins*. The three first are distinguished by the length of their wings, which enables them to fly well, while in the two latter these members are so short, that they seem perfectly useless for any other purpose than that of fins.

1. The ANATIDÆ are distinguished by a thick bill, which is horny only at its extremity; the remainder of the mandibles being invested with a soft skin, which in

other birds is found only at their hinder part. This skin in the ducks is extremely sensitive, and by it the animals take cognisance of the food contained in the mud, into which they plunge their bills. The edges of the bill are roughened, either by plates or small teeth arising from it; and the tongue is large and fleshy. These birds live more in fresh waters than in the sea; and many of them (such as geese and swans) are exclusively vegetable-feeders. The ducks, on the other hand, subsist in part upon animal diet; and one tribe of them, the mergansers, feed almost exclusively upon fish. Under the general designation of *ducks*, *geese*, and *swans*, all the birds of this family may be arranged; and as these typical forms are so well known, it is unnecessary to dwell longer on it, although the habits of many species are extremely interesting. This family is very extensively diffused over the earth's surface, and supplies man with an important amount of food, and with the greater part of the *down* which contributes so greatly to his comfort and luxury.

2. The LARIDÆ, or *Gull* tribe, more resemble the higher orders of birds in their general structure, but are deficient in that which constitutes the perfection of the order—the power of swimming and diving. The wings are very long, and their powers of flight considerable. The feet, although webbed, are so constructed as to enable them to walk with ease along the shore in search of food; the legs are slender, and sometimes so long as to resemble those of the waders; the hind toe is very small, and sometimes wanting. Many of the birds of this tribe have a tendency to associate in flocks. In consequence of their capability of protracted flight, they are met with at a greater distance from land than most others; many species are almost constantly on the wing, and brave the most violent storms. They seem to devour almost every description of animal and vegetable food. This family includes, with the *Gulls*, the *Skuas*, *Terns*, *Petrels*, and also the *Albatross*, which is the largest of all aquatic birds, and in its general habits may be described as a sort of marine vulture. It is extremely voracious, and devours almost any thing that falls in its way. Though its wings are powerful, its flight is by no means lofty. No species of it exist in the northern part of the Atlantic; but it is very abundant beyond the Tropic of Capricorn, and is one of the great enemies of the flying-fish.

3. The PELICANIDÆ, or *Pelican* tribe, are characterised by having the hind toe united to the rest by one continuous membrane: notwithstanding this conformation, which renders their feet perfect oars, they are almost the only Natatores which perch upon trees. All of them fly well, and have short legs. They are a large, voracious, and wandering tribe, living for the most part on the ocean, and seldom approaching land but at the season of incubation. The *Pelicans* themselves are remarkable for the length of the bill, which is armed with an abrupt hook at the end; the width of the gape is excessive; and the skin hanging from the lower jaw, and forming the throat, is so extensible as to dilate into a pouch capable of holding a large quantity of fish. The *Cormorants* are allied to these, and are remarkable for being not only voracious but docile, so that they have been trained for fishing, as hawks for fowling. These are very widely distributed over the earth's surface, whilst the pelicans are restricted to the warmer latitudes. The *Frigate-birds* are nearly allied to the Cormorants, but differ from them in the excessive spread of wing (which renders them the most powerful flyers in this order—perhaps not being surpassed by any other bird), and in the form of the tail and bill. They feed upon fish, especially flying-fish, both darting at it themselves, when near the surface, and obtaining it from other birds, whom they compel to drop their prey. The *Gannets* are allied to the frigate-birds; but the *wings are less* extended, and the powers of flight in*rior*. *Some species* are termed *Boobies*, from the stu*ity they exhibit* when attacked. A species about the *of a goose* is very common in the British seas, and *ds especially* on the Bass Rock, in the Firth of Forth. The Gannets take their prey by ho the air at some little distance above the sur then dropping down upon any fish that they rising within their reach. The air-cells are ver developed, especially under the skin of the brea is almost completely separated by them from th beneath; and it is probable that they may se elastic cushion, to break the force with which of the bird would otherwise impinge on the w

4. The COLYMBIDÆ, or *Divers*, may perhap garded as intermediate in structure between t tribe and the next family. They are all mari with a lengthened, strong, straight bill. The w in general remarkably short; and the feet plac behind the point of equilibrium of the body, t will not allow the birds to walk upon land even as ducks; but they can pursue the fishes upo they feed, even beneath the water, with great s They are few in number, and are chiefly con the seas of northern regions.

5. The ALCIDÆ, or *Auk* tribe, exhibit the m markable adaptation of the structure of the bir aquatic life, with which the entire order pres This is best seen in the *Penguins*, whose wings a small, and covered with mere vestiges of fe which resemble scales; so that they serve as adm fins or paddles, but are totally useless for flight. feet are placed very far back, so that when upo the bird stands nearly erect. Having no po flight, and not being able to run, the penguin is overtaken with ease upon land; but once in the it distances its pursuers, swimming with the sw rapidity of a fish, and springing several feet ove obstacle that may impede its course.

CLASS III.—REPTILES.

The class of Reptiles, which is the next to be sidered, presents us with more diversity of form am its separate orders than any other division of the tebrated sub-kingdom. Scarcely any animals are unlike in external aspect than tortoises and serp yet we shall find that these extreme forms are conn with each other by a gradual series; and the int differences are not so great as to prevent their as tion into one class, distinguished by characters are common to all. These characters are—thei power of maintaining heat, or cold-bloodedness, a from the imperfect aeration of their blood, of only a portion is sent to the lungs at each impul the heart (see article PHYSIOLOGY); their oviparo production; the respiration of air exclusively d the whole period of life, no metamorphosis taking in this class; and the protection of the skin by scales or plates. By the first two they are distingu from Mammalia and Birds, and by the others Fishes and Amphibia.

The deficiency in the oxygenation of the blood, bined with the slowness and feebleness of the ci tion, is connected with general inactivity of the tive functions, as well as with obtuseness of sensatio sluggishness of locomotion. It is a curious result feeble exercise of these functions, that, as in Amp they may be suspended for a considerable time w apparent injury to the animal; and that parts sepa from the body retain for a long period much o low degree of vitality which they usually exhibit i nexion with it. Although at present Reptiles a to perform a comparatively insignificant part i economy of nature, especially in temperate cli where their numbers are few and their powers l we learn from the records of geology, that the a period in the earth's history, long antecedent creation of Birds and Mammalia, when gigantic m of this class not only constituted the chief tena the earth, but extended their dominion over the of the sea.

The three well-known forms, Tortoises, Liz

h afterwards ejects the superfluous fluid, these prevent the food from being regurgitated with it. most important species of this group are the *midas*, or green turtle, so much valued as an of food; the *chelone imbricata*, or hawk's-billed the plates upon whose carapace furnish our tor- all; and the *sphargis*, or leathery turtle, which shell covered by a thick leather-like skin. They chiefly found in warm latitudes.

EMYDÆ, *Fresh-water Turtles*, or *Mud-Tortoises*, rmediate in form between the family just de- and the Land-Tortoises. The character by which ay be most constantly separated from the marine , is the distinctness of their toes, which are ter- d by claws; but a web still exists between the hich assists them in swimming, and also prevents t from sinking into mud. Rivers, ponds, and g streams, are the haunts of these animals, of one species is common in the south and east of , and is fattened for food in Germany and Russia, it is considered a delicacy. The food of the e consists of molluscs, aquatic insects, small fish, , and vegetables. The species at present existing attain any great size, their shells varying from d a half inch to a foot in length; many of the pecies are much larger. In several of the Emydæ apace and the plastron are but loosely united; pieces of the latter are moveable upon one an- This is the case in the *Terrapins*, or Box-Tor- which are able to draw the head and limbs com- into the shell, and to close the latter by folding erior, and in some instances the posterior, divi- the plastron against the carapace.

The flesh forms an article of food ece. In the East Indies are found species which to a much greater size. An individual in the ion of the Zoological Society of London, measures inches along the curve of the back, the breadth shell being 2 feet 1 inch, and the weight of the animal 285 lbs.

Order II.—Enaliosauria.

order Enaliosauria has been founded upon two rdinary fossil genera, the *Ichthyosaurus* and the *aurus*. Of these little else than the bones has reserved to us; and it is therefore impossible to with certainty in regard to many parts of their sation. The character by which they are espe- connected with the Chelonia is the flattening of xtremities into fin-like paddles, resembling the

of turtles. They must have been, therefore, marine animals, endowed with scarcely any power of movement on land; but, although in many points analogous to fish, it is nearly certain that they breathed air like reptiles in general, and that they must have occasionally come to the surface to respire. Moreover, from the remains found in proximity with them, it may be surmised with probability that they fed upon marine animals alone, especially upon the various forms of Cephalopoda, which were particularly abundant at the epoch of their existence.

The general form of the *Icthyosaurus* (or fish-lizard) appears to have been not unlike that of a crocodile, with the substitution of fins for feet. The head is lengthened into a narrow pointed muzzle, and the jaws armed with sharp and formidable teeth; it had eyes of enormous size, which must have given it an extraordinary aspect, and probably enabled it to see by night. The skeleton of the commonest species (*I. tenuirostris*) usually measures 3½ feet in length; but portions of another kind have been found, which must have belonged to animals of above 20 feet. It is probable that the skin was destitute of scales, like that of the Amphibia; and, from recent inquiries, it appears that it possessed a sort of cartilaginous fin upon its back, like that of many Cetacea. This animal may thus be considered as presenting a very remarkable combination of the characters of other classes. Its remains, which are found in the lias and oolitic formations, are more abundant in England than in any other country in Europe.

The *Plesiosaurus* was distinguished by the extraordinary length of its neck, which, in the commonest species (*P. dolichodeirus*), occupies nearly half the entire length. The head is very small in proportion, and the tail is short, stout, and pointed. The cervical vertebræ exceed in number those of any other animal known; and, in their conformation, have a good deal of resemblance to those of the body of a snake. It is the conjecture of Mr Conybeare, by whom the first scientific investigation of the characters of this strange creature was made, that as it breathed air and had frequent need of respiration, it generally swam upon or near the surface of the water, arching back its long neck, like the swan, and plunging it downwards at the fishes that passed within its reach. The greater length of its extremities would enable it to move on land with somewhat less difficulty than the Icthyosaurus; and it might have very probably lurked in shallow water along the coast, where it could find shelter from its enemies, and a place of ambush from which to dart out its long neck upon its own prey. Its length seems generally to have been about ten feet.

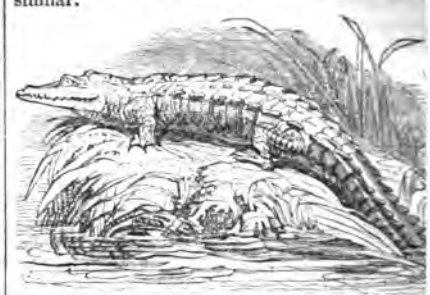
Order III.—Loricata.

The order Loricata, including the Crocodiles, Alligators, and Gavials, may be regarded as in many respects intermediate between the fresh-water Tortoises and the true Lizards. The body is enclosed in a sort of plate-armour, of which the separate portions are closely fitted together, and are capable of great resistance. Another character by which they are distinguished is the flattening of the foot, which is furnished with a kind of web between the toes, like that of the Emydæ: in the true lizards no such provision for aquatic habits is found. This order includes the most bulky reptiles at present known to exist. Some of them attain the length of thirty feet, and a circumference of seven or eight; so that, with the exception of the elephant, the rhinoceros, and the hippopotamus, there is no terrestrial animal exceeding these in dimensions.

Although capable of moving on land, however, the greater number of them prefer the water, and show their chief activity in it. Besides the expansion of the foot, they are adapted for swimming by the lateral compression of the tail, which thus acts as a large and powerful fin. The crocodiles and their allies are all inhabitants of the rivers and fresh waters of warm climates; and they are all purely carnivorous. They destroy their prey by holding it beneath the surface of the water until it is drowned; the position nostrils, and the arrangement of the air-passag such that they are themselves enabled to breath the process. They cannot swallow under wat ever, and their habit is to hide their prey in the bank, until it has become putrid, and then it at their leisure.

The conformation of the neck is such, that cannot be moved very far from side to side, th play in the vertical direction is not limited. mal finds it difficult, therefore, to turn itself ra land; and thus a sure means of escape presen in those rare cases in which it leaves the wate suit of human prey. The tail, however, is very from side to side, and is of great importance in sion. It also serves as an important weapon, armed, like the back, with very strong upright which form sharp ridges or crests in their centr this weapon the crocodiles can inflict terrific upon their enemies. This group is entirely con the countries bordering on the equator. The which compose it may be considered in three sions—the *Crocodiles*, chiefly inhabiting the N other African rivers; the *Gavials*, found in the and other Asiatic rivers; and the *Caymans* or *Al* confined to the New World.

The characteristic differences of these three d are best marked in the form of the head. The have the muzzle exceedingly prolonged and somewhat resembling in form the beak of the bill. In the true *Crocodiles* it gradually widen the point towards the eyes; and in the *Caym* snout is much more rounded, and the head is in proportion to its length. These last appe adapted to aquatic habits than the Crocodiles vials, for the feet are not webbed to nearly th extent as in the latter, and the ridge which in the surface of their hind legs is wanting in the tors. With these exceptions, however, the gene formation of all, as well as their mode of life, similar.



Alligator.

Order IV.—Sauria.

The order Sauria comprehends all the animo monly known as Lizards. They are intermediate the Loricata and Serpents, for they have a lea body, terminating in a tail, like the former; instead of being enclosed in large shields o is covered with small scales, as in the latter. over, they have usually four legs; but in some one pair disappears, and in others they are all c beneath the skin, so that the body presents a s aspect. In this group are found some of the mo and certainly the most beautiful, of the Repti Many of them are tinctured with the most colours, and as they are called into the greates in the bright sunshine, nothing can surpass th dour of their ever-changing hues. These colo an interesting relation to the habits of the ani ing a general resemblance to that of the pla frequent; thus tree-lizards are almost always colours, in which green predominates; ground brown, more or less speckled; and those who stony places are of a greyish hue.

The greater part of the Sauria are carnivorous, feeding upon other animals of inferior size and strength to themselves, and almost always preferring living prey. Many of them pursue nothing but insects; others lie in wait for small birds. The Iguanas, however, feed almost wholly upon vegetables. Many of them are possessed of very great agility upon land; some of them can ascend perpendicular walls, and even run along the ceiling with their backs downwards; none of them are inhabitants of the water, though a few occasionally resort to it. The activity of the smaller insectivorous lizards, when in pursuit of their food, is exceedingly curious and interesting. They watch with all the caution of a cat, and dart upon their prey with the quickness of lightning. Their movements are effected chiefly by means of their feet, and in the higher tribes exclusively so; but in those species in which the legs are short and the feet very small in proportion to the length of the body, progression is greatly assisted by the lateral motion of the trunk, which works its way along somewhat in the manner of that of the serpents.

The order Sauria may be subdivided into five families—1. The LACERTINIDÆ, characterised by the small head and thick neck, but particularly by the very long slender forked tongues of the animals composing it. This group includes the common lizards of this country, and most of the Saurians whose habits are peculiarly active. 2. The IGUANIDÆ, having the same general form, but short thick tongues. This group includes some of the largest of the Sauria, both recent and fossil. 3. The GECKOTIDÆ, which are all nocturnal animals. These have not the attenuated form of the previous families, but are flattened, especially on the head. Their legs are short, and their movements comparatively tardy. Their colour is usually very sombre; and they are reputed, but without foundation, to be venomous. 4. The CHAMELEONIDÆ, whose tongue is of immense length, but obtuse at its point. The feet and tail are both peculiarly adapted for climbing; the former having two of the toes opposable to the rest, and the latter being round and prehensile. Their movements are very slow, except when the tongue is darted out to secure its insect prey. 5. The SCINCOIDÆ, or Serpent-lizards, which are recognised by the shortness of the feet, the non-extensibility of the tongue, and the equality of the tile-like scales which cover the whole body and tail.

1. The LACERTINIDÆ are the most agile, most innocent, and most beautiful of the Saurians. Though they share, in common with the others, the dislike in which the animals of the class of reptiles are held by most persons, they never injure man, and are in some cases of considerable service to him. The larger ones live on the ground, usually preferring the shelter of underwood or of stones, and some frequenting marshy situations; whilst the smaller kinds resort to trees in search of their insect food, and, in the liveliness of their colours and the rapidity of their motions, bear no inconsiderable resemblance to birds. Two small species inhabit this country—the *lacerta agilis*, or sand-lizard, a beautiful little animal, which is sometimes of a brown but sometimes of a greenish hue; it is found on sandy heaths, and occasionally seen basking on the sunny faces of green banks. A more common one, however, is the *lacerta vivipara*, which inhabits most districts of England, and even extends into Scotland; it is also one of the few reptiles found in Ireland. It frequents heaths and banks, and may be seen on the watch for its insect prey, during the warm parts of the day, from the early spring until summer has far advanced. Its name is derived from a peculiarity which it shares with the viper—its eggs are retained and hatched within the body, so that the young are produced alive.

Some gigantic fossil bones have been discovered, which seem to be the remains of enormous saurians, allied in structure to the Lacertidæ of the present time. From the proportional length of the head of one of these, which is nearly the sole part preserved, this lizard must have been at least seventy feet from head to tail.

2. The family of IGUANIDÆ approaches pretty closely to the true lizards in many of its general characters; but it contains several most extraordinary forms, widely differing from each other. The true iguanas are confined to America; but some genera of this order are found over the greater part of the tropical zone.

Among these may be noticed the genus *Draco*, the animals included in which are distinguished at the first glance from all other saurians, by the possession of a pair of wing-like appendages to the sides of the body. These are formed by extensions of the skin, supported by the false ribs, which are greatly prolonged. They can be folded up or extended at the will of the animal, but they cannot be made to strike the air and to elevate the animal like a bird or bat. They serve rather as a kind of parachute, on which this little dragon, not many inches long, flutters from branch to branch in search of its insect prey; and also as a support to it when shooting, like the flying-squirrel, from tree to tree. These animals, the only living representatives of the fabulous dragons of the olden time, are found in the woods of tropical Africa and Asia, especially in the Indian archipelago.

This is perhaps the proper place to notice the very extraordinary fossil, to which the name *pterodactylus* has been given. In its general character it was certainly a lizard; but it seems to have been adapted to raise itself and fly in the air, like a bat or bird. The membrane of the wing was not extended, however, over the whole bony apparatus of the limb, but only one finger, which was enormously developed to support it. It is ranked by Cuvier among the most extraordinary of all the extinct animals that had come under his consideration; and the one which, if we saw them all restored to life, would appear most strange, and most unlike to any thing that exists in the present world. In the form of its head and the length of its neck, it resembled birds; but it had the bones and teeth of a lizard; its wings approached those of bats in form and proportion; and its body and tail resembled those of ordinary Mammalia.

In general external form, the pterodactyles probably most resembled a vampire bat; but in most of the species, the snout was elongated like that of a crocodile, and armed with conical teeth. Their eyes were of enormous size, apparently enabling them to fly by night. From their wings projected fingers, terminated by long hooks, like the curved claw on the thumb of the bat. These must have formed powerful members, with which the animals were enabled to climb, or creep, or suspend themselves from trees. With regard to their food, it has been conjectured that they preyed upon insects; and the number of fossil remains of insects in the strata in which they are found, proves that such a source of aliment was within their reach. The head and teeth of two species, however, are so much larger than would be required for the capture of insects, that they may have possibly fed on fishes (as there were at that epoch few or no small land animals), darting upon them from the air after the manner of many sea-birds.

From this account of the pterodactylus, it is evident that it is a most remarkable connecting link between the classes of birds and reptiles. That it is to be associated with the latter can scarcely be questioned; but if, as has been recently stated, the covering of the skin was more analogous to hairs or feathers than to scales, its affinity to birds must have been extremely strong.

The true Iguanas are confined to the New World, and frequently attain considerable size. They have a kind of spine or crest along the back, and a hanging pouch under the throat, which seems analogous to the dewlap of oxen; this pouch can be inflated, but under what circumstances is not exactly known. They have also in some degree that power of changing the hue of the skin, which is so remarkable in the chameleon. They are very agile, the legs being long in proportion to the body, and their food is almost exclusively vegetable. Some of them attain the length of five or six feet, of which the tail constitutes a large proportion. Their flesh is much esteemed as food; and, in the countries

where they abound, they are sought for with this object. They are extremely tenacious of life. When attacked, they assume a formidable, though not a dangerous, aspect. They open their mouths, vibrate their tongues with rapid motion, inflate their throats, and erect their crests, while their eyes glance with great brilliancy. All this, however, is a demonstration for defence and not for attack. They are never known to combat with any animals but those of very small size.

Some gigantic fossil remains, allied in conformation to the Iguana, indicate the former existence of animals of similar character, which attained enormous bulk. The chief of these was the *iguanodon*, of whose bones fragments have been found in Tilgate Forest. The teeth are so precisely similar to those of the iguana in the principles of their construction, as to leave no doubt of the near connexion of this gigantic saurian, which must have probably attained a length of at least seventy feet, with the herbivorous lizards of our own time. The examination of these teeth discloses some remarkable mechanical contrivances, adapting them to the function of cropping tough vegetable food, such as that afforded by the plants found imbedded with it.

The third family, the Geckotidæ, consists of a large number of animals bearing a strong resemblance to each other in general characters. They are all nocturnal, and pass the day in obscure places; their eyes are large, and their pupil contracts under the influence of light, like that of cats, into a very small aperture. Their flattened form and broad head give to them a very striking and peculiarly disagreeable appearance, which is aided by their sombre and somewhat toad-like hue; hence, although timid and harmless, they are always regarded by the vulgar as having a venomous character, but without the least foundation in truth. Most of them possess claws at the extremities of the toes, and these are capable of being retracted like those of the Felinæ. They appear more useful to their possessor in climbing, however, than in securing their prey, which consists principally of insects. The Geckos are found in most warm countries in both hemispheres. They frequent buildings; and some species have a peculiar organisation of the feet, by which they can climb smooth perpendicular walls, or even run beneath ceilings. They are often useful in clearing houses of musquitoes and spiders; but it is said that articles of food over which they have passed acquire poisonous properties, in consequence of an acrid exudation from the feet. It is difficult to know how much credit to give to such statements; equally positive ones, which are entirely destitute of foundation in fact, being circulated in this country in regard to the toad.

The Chameleonidæ, or *Chameleon* tribe, are few in number; but they present so many anomalies of organisation, that it is necessary to separate them from all the other saurians, and to rank them as a distinct family. They are characterised, in the first place by the structure of the feet, which are adapted for climbing, like those of the scansorial birds (such as the parrot), having two of the toes opposed to the other three. The *tongue* also affords a remarkable character; it is fleshy, *and capable of enormous* elongation; the extremity is *thickened or club-shaped*, and is furnished with a viscous secretion at its extremity. It is by this c the chameleon entraps its insect food; for, by darting out the tongue, the insect is glued, a to the end, and instantaneously conveyed to t This is the only part of the body that move the limbs are often quite motionless for hour the chameleon walks, it advances with the gr cumspection, and there seems a want of pow bine the actions of the different members. once attached to a branch or twig by the gras feet, its seems to have little disposition to qui

The chameleon has been most remarkable, for its power of changing colour, which was k the ancients, and is commonly supposed to be to it; but, as already stated, other animals pos a greater or less degree. Much exaggeration vailed, as might be expected, in the description phenomenon. All the colours of the rainbow, as white and black, have been represented to sumed by it. Its natural hue, when at rest an shade, seems to be a bluish grey; from this i changes to a brownish grey or into a green. times the colour fades to a pale grey, and som it deepens to a dark brown; but these are the ex The phenomenon has been variously accounted late, it has been generally supposed that the hu skin depends upon the degree in which the co the blood is combined with that peculiar to th brane; and that it is altered by a change in th tity of blood sent to the surface, which is incre the distension of the lungs occasionally practised animal. But the recent inquiries of Milne-E have shown that this is only a partial cause; a the change is principally owing to an alteratio relative position of two layer of colouring matte the skin contains, so that they may be displaye or in various degrees of combination.

The last family of the Saurian Reptiles—S coidæ, or *Skink* tribe, conducts us so gradually the Serpents, that it is difficult to know where the line of demarcation between them. They cognised by the shortness of the feet, the rou the body, and the equality of the tile-like sc the whole surface; their tongue is not capab tension. They have all more or less of a s form; and in some of them only two feet are d The true *scincus* probably approaches to the saurian type more closely than the rest of th It is furnished with four short but strong feet, with considerable agility. The *seps* has a more like body than the skink, and the feet are sm wider apart. These gradually become simpler ture in various species; the number of toes duced, until the feet seem like simple hooks from the body. The *chalcis* is another snak small-legged saurian, which, in some peculiar conformation, approaches a different group of In the *bipes*, the anterior pair of feet is not d and in the *chirotes*, the posterior pair is wan both these, the general conformation of the the habits, so far as known, correspond with the common blind-worm, which is ranked a Ophidia.

bsequent orders. 2. The CROTALIDÆ, contain-
attlesnake, *Viper*, and all the venomous species.
YDROPHIDÆ, or *Water-snakes*. 4. The AMPHIS-
or *Double-walkers*. 5. The ANGUINIDÆ, or
ms. These last approximate the Lizards, in
ssion of rudimentary legs under the skin, as
n other points of their organisation.
OLUBRIDÆ are particularly distinguished by
r of dilating the opening of the jaws to an
s extent, so as to permit of animals being
swallowed which are much larger than the diameter of the serpent itself. This is accomplished by the separation of the jaw-bones into various pieces, which are very moveable on one another and on the skull. The most remarkable species of this family, which is the most numerous of the order, are the *Boa Constrictors** of the New World and the *Pythons* of the Old; these, when full grown, attain the length of from thirty to

Boa Constrictor.

forty feet, and in thickness nearly equal a man's body. They do not fear to attack any animal; and, if they can once coil themselves round it, crush it by the enormous combined power of their muscles, in spite of all its means of resistance and defence. Their power is much increased by coiling the tail round a tree, so as to give a point of support from which the muscles may act more efficiently; and it is in this manner that they commonly wait for their prey. When they have seized and entirely destroyed it by crushing, in which process all the principal bones are broken, they begin to swallow it. This process lasts some time; and when it is complete, the position of the mass in the alimentary tube is at once known by the external protuberance. The process of digestion takes some days or even weeks for its performance, according to the size of the prey; and during that time the monster lies in a very inactive state, only issuing forth to seek a new victim when the digestion of the last has been for some time finished. The hair, horns, and other least digestible parts, are usually disgorged during the process. The Boas are distinguished from other serpents by the presence of two projecting bones near the vent, which are called *claspers*, and which may be regarded as the rudiments of posterior extremities.

The *Colubers*, strictly so called, are usually of comparatively small size; but their habits are the same in proportion. The common snake of this country attacks small quadrupeds, frogs, birds, &c., in precisely the same manner that the boa seizes its larger victims. It is fond of marshy situations, and takes to the water readily, inflating its lungs so as to render itself buoyant. The flexibility of body, which is their means of obtaining support, is greater in the non-venomous serpents than in the Crotalidæ, which have another mode of procuring it. This is shown by suspending a coluber by its tail; it can bend its body so as to bring its head to the point at which it is held; this the venomous serpents cannot do. All the smaller species of this family are perfectly harmless to man, and may be handled without fear. Many of them are remarkable for the brilliancy of their colours, and others for the extreme regularity of their markings.

* The name *Boa Constrictor* is commonly applied to the immense serpents of the East Indies; but only those of the western hemisphere possess the characters which the naturalist now assigns to the genus Boa.

The CROTALIDÆ, or *Venomous Serpents*, do not differ much in external characters from the preceding family; but the character of their teeth is quite sufficient to distinguish them. The poisonous properties of the different species vary considerably; in general they are more severe in the serpents of warm climates than in those of temperate regions. Cases of death from the bite of the British viper are very rare, and are generally to be attributed in part to some previously existing derangement of the system. There are many serpents in the torrid zone, however, whose bite is fatal to man and other large animals in a few hours, and to small animals much sooner.

This family contains two principal series—the *Rattlesnakes* and the *Vipers*. The former are generally regarded, but probably incorrectly, as the most venomous of all serpents. The rattle at the end of the tail, which is their distinguishing characteristic, is formed of several separate pieces of a dry horny substance, one of which is received within another. They are quite loose, and receive no nourishment after they are once formed. A new piece is said to be added every time the skin is cast, which usually takes place twice a-year. The sound made by the rattle is not great in the ordinary motion of the serpent, and cannot be heard at more than two or three yards' distance. Several species of *Crotalus* are described, varying in length from four to eight feet. They are all natives of America. Their ordinary food consists of birds, squirrels, and other small animals. It was once supposed that they possessed the power of charming or fascinating these animals, so as to draw them by degrees to enter their throats. This is certainly an error; but it is equally certain that most animals are so terrified at the sight of the rattlesnake, as to lose the power of escape, and to become an easy prey when it darts upon them.

The *Vipers*, being destitute of the peculiar characteristic of the Rattlesnakes, are more like the Coluberidæ; their forms, however, are less elegant, their colours less splendid, and their movements less active. In general, they are remarkable for the dark lurid tints of their covering. The most celebrated species of this group is the *cobra di capello* or *spectacle-snake* of the East Indies. Its first name, given to it by the Portuguese, signifies hooded snake, and is derived from the power of dilating the skin behind the head, when irritated, so as to give the appearance of a hood or cowl. The common English appellation is bestowed in consequence of a mark, in the shape of a pair of spectacles, behind its head. This is one of the most deadly serpents of the East. An equally, if not still more, venomous snake, however, exists in some of the West Indian islands. The bite of the venomous serpents varies in its consequences according to the state of health of the bitten subject, the depth and number of the wounds, the time which has elapsed since the animal last made use of its fangs, and consequently the amount of poison which has penetrated into the system.

The HYDROPHIDÆ, or *Water-Serpents*, are comparatively few, and are limited in their geographical range. They are mostly found in the seas and rivers of the East Indies, and in some localities they are by no means uncommon. They are chiefly known by the very decided vertical compression of the tail and hinder part of the body, which may thus be compared to the tails of fishes; hence they swim with considerable facility, occasionally coming to the surface to respire. They possess poison-fangs, and are more dangerous than crocodiles or sharks to persons entering the water where they abound. One species exists in the rivers and canals of India, and attacks animals which come to bathe or drink, as well as devotees whilst performing their ablutions; others are confined to the sea, where they feed upon fish. It is stated that they will occasionally make their way into boats. Their colours are generally bright.

The AMPHISBÆNIDÆ, or *Double-Walkers*, are a still *smaller group*, intermediate in some respects between *the true serpents* and the slow-worms. They derive their name from the power of moving either back or forwards with equal facility. The two extr of the body are so much alike, that they would distinguished by a superficial observer, the eye so very small as sometimes to appear wanti whole body is of nearly equal diameter. This g restricted to the warmest parts of South Am Notwithstanding the common idea of its venomo perties, it is quite harmless, and subsists on w other small insects. It has not the power of s ing the bones of the jaws, which distinguishes th serpents.

The ANGUINIDÆ may almost be called either or serpents, so remarkably do they combine th racters of the two orders. In one species the ments of hind legs form a visible projection ne vent; and in another the anterior ribs are con by a cartilage which is the rudiment of a sternum common *slow-worm* or *blind-worm* of this count received its second name from the supposed abs eyes; this is an absurd error, however, as the though small, are very brilliant. It is a pe harmless animal, feeding on insects, slugs, &c. said to swallow frogs, birds, and mice; but this possible, as the bones of its jaw do not separate middle, and its swallow is consequently small a dilatable. When alarmed, it throws the whole muscles into contraction in a peculiar manner, then very brittle, so that it frequently loses its t various accidents; in the course of a year, how this member is replaced. There is a larger spe this family existing in America, which attains the of two feet, and from its extreme fragility is call *glass-serpent*.

The Serpents are connected with the Amphi the curious genus *Cæcilia*, or naked serpent, whic be described as a member of that class.

CLASS IV.—AMPHIBIA.

The animals composing the class Amphibia we cluded by Cuvier and many other zoologists unde general designation of Reptiles. There seems, how sufficient reason for separating them into a di group of equal rank. They may be regarded as inte diate in their structure, and in their habits and m life, as well as in many of their forms, between F and true Reptiles; and they bear a still more remar relation to these classes, in that change which ma them undergo at a certain period of life, by which become transformed from the nature and habits o former to those of the latter class, by a metamorp analogous to that of insects.

The class we are now considering offers us the instances of animals possessing two sets of respir organs, one adapted to breathe air and the oth aerate the blood by exposing it to water. In m the species composing it, lungs and gills do not ex the same time, at least in a state of activity; the gradually disappearing as the former are deve But in a few species the gills are retained durin whole of life, even after the lungs are capable of ing the blood. These are, then, the only true a bious animals; but the term AMPHIBIA may be properly applied to all such as undergo this ki metamorphosis, breathing by gills alone at the mencement of life, and afterwards acquiring lun which air can be respired.

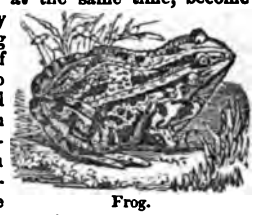
The general peculiarities of the Amphibia m thus stated:—Like fishes and reptiles, between they are intermediate, they are oviparous and blooded, but their skin is soft and naked, being de of scales or plates. Most of them undergo a met phosis which has reference to a change of con from the form of a water-breathing fish to a breathing reptile; and, when they have attained perfect condition, they closely resemble true r in general character. In many species, however

age is seen from the time that the animal emerges
m the egg to its adult age. With the exception of
frogs, they have much the form of lizards (among
ich several of them were formerly classed), and have
erally four feet and a lengthened tail.
The class, which contains but a small number of dif-
nt genera, may be best subdivided into orders chiefly
rding to the degree to which the metamorphosis
ceeds. Thus, in the first, ANOURA, embracing the
gs and *Toads*, the gills are entirely lost in the per-
t state, and the tail also disappears. In the URODELA,
luding the *Salamanders*, *Water-Newts*, &c., the gills
appear in the perfect state, but the tail is retained.
e AMPHIPNEURTA, to which the *Proteus* and *Siren* be-
g, retain their gills during the whole of life; the tail
ntinues to form a large part of the body, and in some
stances only two legs are developed. In the ABRAN-
A, an order which consists only of two little-known
era, no gills have been found at any period of life,
the body and tail are evidently formed for swim-
g. And in the APODA, including only one genus,
Cæcilia, the body is altogether destitute of feet, and
a serpent-like form.

Order I.—Anoura.

he principal subdivisions of the first order are the
IDÆ, or *Frog* tribe, and the BUFOIDÆ, or *Toad* tribe.
former frequent water, and are adapted for swim-
g in it; the latter are usually found at a distance
m water, and are much less adapted for active move-
nt of any kind. The metamorphosis of both these
ended with the same general phenomena; and as
animals themselves are so well known, a description
his process will be a sufficient account of those which
abit Britain. It is one very easily observed, for, by
aining a little water containing young tadpoles, the
e process may be made to go on under our eyes,
the young naturalist is earnestly recommended to
ch it for himself.
he spawn, soon after its deposition in pools, consists
a transparent gelatinous mass, enveloping a num-
of little black dots, which are regularly distributed
ough it, and which are the eggs. Those are abun-
tly found in stagnant pools in the month of April,
g usually deposited (in this country) at the end of
rch, and hatched about a month afterwards. When
tadpole first emerges, it is seen to present, in every
pect, the appearance of a fish. It has a large oval
d, and an elongated tail, flattened vertically, by the
rations of which it swims actively through the water.
gills are found hanging in tufts on each side of the
d; and, if examined with a microscope, the motion
the blood through them may be very beautifully seen.
circulation may be observed, also, with great faci-
y in the fin-like expansion on the upper and under
ge of the tail. Very soon, however, the gills are with-
wn, as it were, into the head, being covered over
a fold of skin, analogous to the operculum, or gill-
er of fishes. The little creature, which at first seemed
derive its subsistence from the fluid absorbed within
body and on its surface, now seeks its food amidst
tened or decomposing vegetable matter; and, to give
ater power of movement, the surface of the tail is
siderably increased.
The tadpole now undergoes but little change in its
ternal form for a considerable time, but increases
pidly in bulk. The first appearance of limbs is seen
a little tubercle or knob which projects at the back
the head: this is the rudiment of the hind leg. It
on acquires somewhat the form of the perfect limb,
e toes budding, as it were, at the extremity; but it
ll continues very short, even in proportion to the
minutive size of the animal. Meanwhile, the fore legs
e also budding out in the same manner, and gradually
ume their distinct and ultimate form. During this
ocess, the development of the body goes on at the ex-
se of the tail, which is gradually removed by absorp-
n, so that the hinder part of the body becomes rounded.
e gills disappear by a similar process.

The little animal has now undergone its complete development, and having, at the same time, become capable of respiring air by true lungs, and of moving freely on land by means of its hinder legs, it comes to the shore to feed on small insects and worms, which are henceforward to constitute its nutriment. Such multitudes of these newly-perfected little beings are often found in damp weather enjoying their new scene of existence, as to have given rise to many stories of showers of frogs having descended from the sky, which are still believed in some parts of the country. They now grow with great rapidity during the remainder of the year; but on the approach of winter they retire to the mud at the bottom of the water, where they congregate in large masses, remaining torpid until the return of spring.



Frog.

The BUFOIDÆ, or *Toads*, are a perfectly harmless and inoffensive race, although certainly not inviting in their general aspect. The idea of their venomous character is altogether unfounded. The body is of a dull hue, its shape awkward, and its movements appear difficult, but it is by no means deserving of that disgust which it has inspired in some naturalists as well as in the popular mind. Unpossessed of any power of active defence, or of rapid escape from its enemies, the dullness of its colour serves to shield it from observation. Its eye bears a remarkable expression of mildness and patient endurance, rather fitted to excite pity and compassion than disgust or repugnance. It issues forth from its concealment at twilight in search of food; and this consists of insects, worms, slugs, &c., the inordinate increase of which it is very useful in repressing. It seems to prefer that which is actually alive and in motion. When about to feed, it remains motionless, with its eyes turned directly forwards upon the object, and the head inclined towards it; and in this attitude it remains until the animal moves, when, by a stroke like lightning, the tongue is thrown forward upon the victim, which is instantly drawn into the mouth. So rapid is this movement, that it requires some little practice, as well as close observation, to distinguish the different motions of the tongue. This organ is folded back upon itself, as in the frog; and the under surface of the tip is imbued with a viscid mucous secretion, which adheres to the prey. This is generally swallowed alive; and its motion within the stomach may often be perceived for some time afterwards.

The toad, like the rest of the Amphibia, becomes torpid in winter; but, instead of returning to the water, like the frog, it chooses for its retreat some retired and sheltered hole, or a space amongst large stones. Like the other Amphibia, too, it is endowed with great tenacity of life, and can exist for a very long time deprived of food and almost of air. The knowledge of this fact has occasioned a disposition to give too ready credence to the various wonderful accounts which have been circulated, at different times, of toads being found alive, completely enclosed in solid rock or in the heart of trees. It is not at all unlikely that a toad which has retired to a hollow in a tree in the autumn, may find itself so far enclosed in the spring as to be unable to escape; and that, through the opening, it may obtain the requisite supply of air, and even of food. In process of time new wood may be deposited around it, so that the cavity shall be completely moulded upon its body; and the opening will be gradually diminished. Still, a very small aperture will be sufficient to admit air, moisture, and minute insects, by which it may be supported for many years, being a long-lived animal; and in none of the cases on record does there seem to have been such a minute examination of the cavity as to disprove the idea that a connexion with the external air still existed. In a similar manner it is fair to explain most of the accounts of toads found in stones, &c.

Order II.—Urodela.

The animals of the order Urodela bear so strong a general resemblance to lizards, that they were united with that group by Linnæus, and are still popularly regarded as such. The *Salamanders* and their allies, however, are easily distinguished by the smoothness and softness of their skin, which is entirely destitute of those scales which all lizards possess. Moreover, they undergo a metamorphosis similar to that of the frogs, except that the change of form does not proceed to the same extent. Like the Anoura, this order may be subdivided into two families, of which one, that of the TRITONS, is of aquatic habits even in the adult state, like the frogs; whilst the other, that of the true SALAMANDERS, bears more analogy with the toads in its aspect and habits.

Of the TRITONS several species exist in this country, and are known under the names of *Evat*, *Eft*, *Newt*, &c. The largest is about six inches in length: it is not at all uncommon in ponds and large ditches, where it lives upon aquatic insects and other small living animals: it even devours the smaller species of newt. The eggs are laid in the spring, upon aquatic leaves, which are folded together by the animal; and the young tadpole, when it comes forth, bears considerable resemblance to that of the frog. The gills, however, are in larger tufts, and they afford a most advantageous opportunity for observing the circulation. The anterior legs are the first developed; and even after they have arrived at nearly their full growth, the gills are very large, and actively performing their functions. The lungs are, however, gradually developed; and, towards the end of autumn, the gills are absorbed, and the animal breathes air only. Still it does not quit the water, but remains an inhabitant of that element, coming occasionally to the surface to breathe.

The *Salamander* is a land animal, of the same general character with the water-newt, but possessing a rounded instead of a flattened tail, and a surface somewhat warty, like that of the toad. It discharges, when alarmed, an acrid secretion from the tubercles in the skin, which is said to be poisonous to small animals. In other respects it is quite harmless, and is not possessed of any remarkable properties. The eggs of the salamander are hatched within the body, so that the young are produced alive, and the progress of the metamorphosis has been considerable before it sees the light. Nevertheless, it at first inhabits the water, and, when it has finally quitted it, frequents damp in preference to dry situations. No species exists in Britain, but the salamanders are pretty extensively diffused over other parts of the globe.

Order III.—Amphipneurta.

The animals belonging to the order Amphipneurta exactly resemble salamanders the development of which has been checked just at the period of their transformation from aquatic to air-breathing animals. They retain their gills during their whole life, and acquire lungs in addition by the partial metamorphosis they undergo. The legs bear but a very small proportion in their degree of development to the tail; and in some instances only one pair is formed. The first-discovered animal of this order was the *proteus*, an inhabitant of the underground lakes of Carniola and Styria, and of the passages between them. So strongly does this resemble the larva of a salamander, that it was at first believed by naturalists to be such; and it was only after the discovery of others of the same character, that its true nature was understood. Unlike most other animals, it appears to suffer injuriously from light; for not only does it prefer dark places, but even dies if it be exposed to open day for any length of time without the power of hiding itself. The *siren* is an animal of similar character, inhabiting the North American rivers, where it feeds upon earth-worms, aquatic insects, &c., in search of which it burrows in the mud. Only the anterior pair of feet is developed, and there is no rudiment of the other. The body has very much the form of that of the eel; and sometimes it attains the length of three feet.

Order IV.—Abranchia.

The order Abranchia contains only two gen these both peculiar to North America, the s and the *amphiuma*. They are not known to any metamorphosis, but breathe by lungs du whole period of life, and have never been seen of legs. These are, however, very short, a almost useless appendages to the body, which like that of an eel. It is not improbable that, salamander, the egg may be hatched within th the parent, and that the young may not co until it has passed through its tadpole state.

Order V.—Apoda.

The order Apoda contains but one genus, th blind-newt, or naked serpent. This was p Cuvier among the Serpents, from the snake-l of the body, which is destitute of any rudimen But, in the absence of scales on the skin, as well anatomical characters, it rather corresponds Amphibia, forming, however, a most interesti tion to the next class. It is not known to un metamorphosis. Its name was conferred by on account of its supposed blindness. The exceedingly small, and are nearly hidden u skin, and it is believed that, in some speci organs are altogether wanting. These animals the rivers and marshy grounds of many tropi tries: further information in regard to them needed. They are said to burrow in the gro to live very much in the manner of earth-wor far as is known, they are perfectly harmless.

From this sketch of the class AMPHIBIA, seen that, in a scientific point of view, it is most interesting in the whole animal kingdom. of little direct benefit to man, it is certainly as as any tribe. And thus, although the forms of the species offend against our notions of bea their love-songs give them the character of "musicians," the aversion and prejudice with wh are ordinarily regarded would be justly replace pleasure of intelligent curiosity.

CLASS V.—FISHES.

The animals of this class are the only Ve which, in their adult state, are formed for r beneath the surface of the water they inhab whale tribe, so much resemble them in aspect and in mode of life, are all air-breathing and they are as certainly drowned by being p from taking in air at the surface, as are an which ordinarily live on land, though, by their conformation, they are enabled to sustain the it for a longer time. The same is true of fro manders, and other reptiles, which pass a larg their time under water. But with fishes, the r the case. In these, as in the Mollusca, the b ceives its necessary purification by being expos air contained in the surrounding fluid. This is its transmission to a series of delicate filament tuting the *gills*, each of which consists of tw blood-vessels (one to convey the blood from t and the other to return it) enclosed in a delic brane, through which the chemical changes the blood and the air take place. But these do not hang loosely in the water, as in the gre of the Mollusca. They are attached to bony laginous arches, which are arranged in pair the head, and are more or less protected by covering; and there is a provision which ensur per change of the fluid in contact with the cavity in which they lie is connected with th mouth, and water is constantly taken in by th ing, and forced by muscular action over the s the branchiæ or gills, passing off through the which are seen behind the head.

The quantity of air contained in water is

al; whilst the position of the other, corresponding with the posterior extremities of land animals, the *ventral*, is extremely variable. Sometimes the ventral fins are placed far back, in the usual situation of hind legs; and sometimes they are fixed far forward, even anteriorly to the pectoral. The pectoral fins are usually connected more intimately with the body than the ventral. These fins are composed of a membrane stretched over a set of bony or cartilaginous rays, which may be regarded as representing the bones of the hand or foot. The bones which connect them with the spine are very short, and are placed under the flesh; so that the chief movement of the fins is, as it were, at the wrist and ankle joints. It is chiefly by their vibrations that the animal is kept depressed in the water, and they also assist in changing its direction from side to side. The formation of the ventral fins is chiefly noticed in those species whose habits involve a considerable change of their depth in water. Sometimes one, and sometimes both pairs of these fins are absent; in the latter case the fish is said to be *apodal* or footless. In some instances the pectoral fins are enormously developed, like the wings of birds, and even enable the animal to raise out of the water and to skim for a short distance its surface.

The *swimming-bladder* is an organ usually supposed peculiar to this class. In the highest forms in which it exists, however, its correspondence with the lungs of air-breathing animals is very evident; and there is little doubt that air is taken into it from without for the purpose of respiration. In its lower or more rudimentary condition, however, its office is more doubtful, especially where it is entirely closed. It is usually supposed to contain air, and to serve as a means of regulating the specific gravity of the animal, the swimming-bladder being compressed when the fish desires to sink, and allowed to expand when it desires to rise. In this manner it would seem that gold-fishes are enabled to rise and descend in the water, without any muscular effort visible to those who watch them. But it is remarkable that this organ is sometimes absent in a species closely allied to one in which it is present; and that the presence of it does not seem to make any difference in the habits. As a general rule, it is more constantly present in river fishes than in the inhabitants of the sea; it is most frequently absent in those which usually swim near the bottom of the water.

The surface of the body is generally covered with horny scales, which vary considerably in form and size in different species. Each scale is composed of several plates, of which every one extends on all sides beyond the one on its exterior; hence the appearance of numerous concentric lines on all sides, which mark the stages of growth, the larger plates being the latest formed. They thus resemble the shells of molluscs in the mode of increase. Each scale is attached to the skin of the fish by its anterior edge, which is covered by the scale in front of it, whilst its posterior edge overlaps the scales behind it. This arrangement is not universal, however; for the scaly covering is sometimes formed of a series of bony or even enamel plates, united together by their entire edges. Such an arrangement was very common in the fishes existing at the time of the coal formation, but is now much more rare.

When we consider that more than two-thirds of the earth's surface is covered with water, often to a very great depth, and that, as far as is known, the whole of this element is habitable by fishes (each stratum having some particular species formed to exist in it), little doubt can be entertained that they form the most numerous class of vertebrated animals. Their numbers are kept up by their extreme fertility. The cod-fish has been ascertained to lay not much fewer than four millions of eggs at a single deposit; and in other species the number may even be greater. Their voracity is

also extreme. Almost all of them are adapted to devour and digest animal food, some of them living chiefly on crustacea, mollusca, and other invertebrate inhabitants of the ocean; and others having it for their especial function to keep down the inordinate multiplication of their own kind. Some of these attain a considerable size. The pike has been found nineteen feet long; and there is evidence of one having lived for 267 years. The sun-fish has reached the length of twenty-five feet; and some rays and sharks have exceeded forty feet.

The classification of Fishes proposed by Cuvier is probably the best that, in the present state of our knowledge of this group, can be adopted. It is obvious that, from the peculiarities of the habitation of these animals, and the very imperfect manner in which the depths of the ocean, over a large part of the earth's surface, have yet been explored, a great number of existing species probably yet remain to be discovered. And it is also certain that the number of species formerly existing in the waters, and of which we have at present but very scanty remains, was considerable, and that their forms often differed widely from those familiar to us. Hence, when these shall have been more completely investigated, it is not improbable that this classification must be greatly modified in order to include them.

The primary division of the class is into the *Osseous* and *Cartilaginous* Fishes, the former having a hard bony skeleton, and the latter having one of less firm consistence, possessing but little calcareous matter. The former group is divided into six orders, which are principally characterised by the structure and arrangement of the fin rays. These are distinguished as either consisting of a single piece—in which case, whether stiff or flexible, they are said to be *spinous*—or as consisting of a number of jointed pieces, divided at their extremities, when they are called *soft* or *articulated*.

1. Acanthopterygii, or *spiny-finned*. In this order, which contains the greatest number of ordinary fishes, there are spinous rays in the first or anterior part of the dorsal fin, and sometimes these have no connecting membrane. The anal fin has also its first rays spinous, and there is generally one such ray in the ventral.

The three next orders are all *soft* or *jointed-finned*, and come, therefore, under the general designation Malacopterygii. They are distinguished from each other by the position or absence of the ventral fins.

2. Malacopterygii Abdominales. In these, the ventral fins are attached to the abdomen behind the pectorals. They are a very numerous order, and include the greater part of the fresh-water fishes.

3. Malacopterygii Sub-Brachiati. In this order the ventral fins are brought forwards under the pectorals, and the fish, which are chiefly marine, enjoy a considerable power of ascending and descending in the water.

4. Malacopterygii Apoda. These are fishes in which the ventral fins are always wanting, as are not unfrequently the pectoral also.

The two remaining orders of Osseous Fishes are separated from the rest by other peculiarities.

5. Lophobranchii (Tuft-Gilled). In these, the gills, instead of hanging in regular fringes, like the teeth of a comb, from the branchial arches, are disposed in tufts, and the gill-covers open less freely than in the preceding orders.

6. Plectognathi. The members of this order, though retaining many of the characters of the Osseous Fishes, exhibit an evident transition to the Cartilaginous, both in the less complete ossification of the skeleton, and by the union of the bones of the upper jaw to each other and to the head. The opening of the gill-covers is still smaller than in the last order.

The *Chondropterygii*, or Cartilaginous Fishes, cannot be considered either superior or inferior to the others, *but form, as it were*, a parallel series with them. Some *tribes exhibit the lowest* organisation which exists in *the class, whilst others present* many points of affinity *to Reptiles. The* different parts of the skeleton, which, *in the Osseous Fishes*, are united by distinct joints, here frequently form one continuous piece. This ... remarkable in the head, which is composed of a ... piece, in which, however, the principal parts for... the bony fishes may be distinguished by various ... furrows, and holes. This group contains three ... distinguished from each other by the conformati... the mouth and the arrangement of the gills.

7. Chondropterygii Branchiis Liberis (Free-G... Cartilaginous Fishes). In these, consisting chi... the Sturgeons, the gills hang freely, and are co... with a gill-lid having a single wide opening, as i... seous Fishes.

In the other two, the gills are attached at the ... edge, and there is a separate opening for the ... the water that passes over each arch. These, ... are termed Chondropterygii Branchiis Fixis, or ... Gilled Cartilaginous Fishes, are distinguished from ... other by the conformation of the mouth.

8. Selacii, or *Sharks* and *Rays*. Here the jaw ... not united into a ring.

9. Cyclostomi (Round-Mouthed). These have a ... fleshy lip, by which they adhere to their prey, ... ing their food by suction, and this is supported ... cartilaginous ring, formed by the union of the ... bones. It is in the fishes of this order that we fi... vertebrated structure in its lowest form.

DIVISION I.—OSSEOUS FISHES.

Order I.—Acanthopterygii.

The Spiny-finned Fishes are divided by Cuvier ... fifteen families, the most important of which w... be noticed.

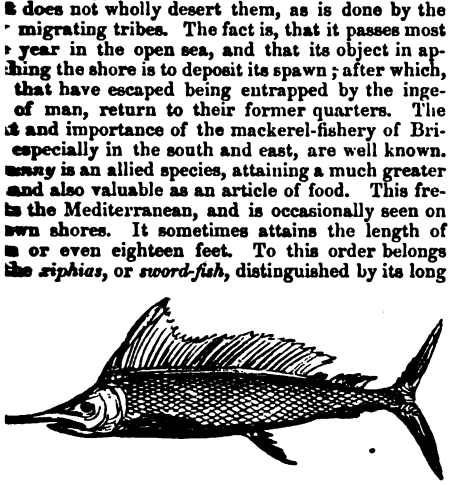
Percidæ, the *Perch* tribe. al seas. One of these, the *C. rostratus*, which has y prolonged snout, has the faculty of shooting s with drops of water projected from the mouth, t then seizes them as they fall. This power is the extraordinary, as, according to the laws of the tion of light, the place of the insect will appear fish different from the reality, the rays passing a rarer to a denser medium; and the drop must herefore, be projected in the line in which the *appears* to be, but somewhat below it. This ish, which is a native of India, is often kept in vases by the residents there, as gold-fish are in ountry, for the purpose of affording amusement dexterity.

next family, SCOMBERIDÆ, or the *Mackerel* tribe, of very great importance to man. It com- a large number of genera, a vast collection of s, and numberless individuals. The aspect of the on *mackerel*, with its spindle-shaped, beautifully- ed, smooth, and small-scaled body, is well known. y rapidly dies out of water, and soon becomes d. Mackerel has been supposed to be a migra- ish, on account of its appearing on our shores in ase shoals at particular epochs. But it may be t all the year round on our coasts, which shows does not wholly desert them, as is done by the migrating tribes. The fact is, that it passes most year in the open sea, and that its object in ap- hing the shore is to deposit its spawn; after which, that have escaped being entrapped by the inge- of man, return to their former quarters. The t and importance of the mackerel-fishery of Bri- especially in the south and east, are well known. *nny* is an allied species, attaining a much greater and also valuable as an article of food. This fre- s the Mediterranean, and is occasionally seen on own shores. It sometimes attains the length of or even eighteen feet. To this order belongs he *xiphias*, or *sword-fish*, distinguished by its long



Sword-Fish.

ed beak. This is a most powerful offensive weapon, with it this fish attacks the largest inhabitants of ean. By its high dorsal fin and expanded tail, able to impel itself forwards with great force; and attacking a large animal, it makes a violent dart st it, quite transfixing it with its sword. It has known in this manner to drive its beak into the ers of a ship, and, not being able to withdraw it, eak it off and leave it. The sword-fish abounds e Mediterranean, but is less frequent in the Atlan-

It is very palatable as food; and often attains the h of fifteen feet. The *dory*, of which one species ghly prized by epicures, is another fish of the same ly. It is remarkable for the filamentary prolonga- s from its dorsal fins. And lastly may be mentioned *coryphæna*, commonly known as the *dolphin*. This large and splendidly coloured fish, which darts ugh the water like a radiant meteor, exhibiting an ordinary play of colours when brilliantly illumi- d. It has long been celebrated for its change of ur when dying. It swims with great rapidity, and y voracious, committing great havoc among the g-fish and others of like size. The influence of t on the colour of animals is remarkably shown in far superior brightness of the Indian *Scomberidæ*, n contrasted with the blackish hue of those of hern seas.

he fishes of the family PHARYNGINÆ LABYRINTHI- FORMÆ, are characterised by a very peculiar structure, from which they derive their designation. The membranes of the pharynx (or back of the mouth) are divided into small irregular leaves, containing cells among them, which the fish can at pleasure fill with water; and, by ejecting a portion of this water, it moistens its gills, and may thus continue its respiration out of its proper element. By means of this apparatus, which resembles that possessed by the land-crabs, these fishes are enabled to quit the pool or rivulet which constitutes their usual element, and move to a considerable distance over land. Such a provision is especially desirable in tropical climates, where shallow lakes are often dried up by a continued drought, and their inhabitants must perish if not enabled to migrate. The people of India, who often witness the appearance of these fishes where they were known not to exist, believe that they fall from heaven. Some of them are able not only to traverse plane grounds, but can climb steep banks or even trees in the course of their journeys. Of these the most curious is the *anabas*, commonly known as the *climbing-perch* of Tranquebar, which climbs bushes and trees in search of its prey, a species of land-crab, by means of the spines on its back and gill-covers.

The members of the family GOBIODÆ, or *Goby* tribe, are known by the thinness and flexibility of their dorsal spines. Many of them are remarkable for producing their young alive, the eggs being hatched within the body of the parent. This is the case with the *blenny*, of which several species frequent the British shores, living in small troops among the rocks. They are remarkably tenacious of life, being capable of being kept a good many days in moist grass or moss, but they are of little value as articles of food. The true *Gobies* are chiefly remarkable for the *nest* which they construct among the sea-weed for the protection of their young, which was observed by the ancients. They prefer a clayey bottom, in which they excavate canals, and in these they pass the winter.

The next family, PECTORALES PEDUNCULATI, derives its name from the peculiar structure of the pectoral fins, which have a kind of wrist formed by the elongation of the bones to which they are attached. This conformation gives these fishes a very strange appearance, and enables them to leap suddenly up in the water in pursuit of their prey, and even to leap over the mud. In many of them the skeleton is demi-cartilaginous. One of the most curious is the *lophius*, or *fishing-frog*, of the British seas, which is met with chiefly on muddy shores. It derives its name in part from its wide gaping mouth, and in part from the peculiar manner in which it angles for its prey. It has some curious appendages to its head, which terminate in long, round, and rather brilliant filaments, having a resemblance to worms. The animal lurks in the mud, and puts these appendages in vibration; they are mistaken for worms by small fishes, which they attract, and these are gulped down the capacious swallow of the lophius. To such an extent is this voracity carried, that the *angler* (as it is sometimes called) is often an article of value for the live fish which it has in its stomach, although its own flesh is worth but little. There is an allied genus, the *chironectes*, of which a species abounds on the north coast of Australia. When the tide ebbs far back in the dry season, these frog-fishes are so abundant, and capable of taking such vigorous leaps, that those who have visited these places have taken them at first sight for birds. The fishes of this genus can inflate their large stomachs with air, in the manner of the Tetrodons.

Order II.—Malacopterygii Abdominales.

This order, consisting of soft-spined Fishes which have the ventral fins under the abdomen, contains five families, all of which are highly interesting to the naturalist.

1. The CYPRINIDÆ, or *Carp* tribe, are all fresh-water fishes. They have the mouth shallow, the jaws feeble, and very often without teeth, but the pharynx is strongly toothed. They are among the least carnivorous of

fishes, feeding chiefly on seeds, the roots of plants, and decomposing vegetable matter. The common *carp* is imported into England from the warmer parts of Europe; it thrives better in ponds or lakes than in rivers, it feeds on insects and worms, as well as on vegetables, and it is very tenacious of life, so that it is easily transported from place to place.

2. The family Esocidæ, or *Pike* tribe, contains the most voracious fresh-water fishes, as well as several important marine species. They are distinguished by the absence of fatty matter in the dorsal fin (which exists in the Salmon tribe), and by the position of this opposite to the anal fin. The *pike* is very destructive of the smaller fishes in the ponds and rivers in which it exists, and sometimes attains a considerable size, weighing between thirty and forty pounds. The *gar-fish*, or *sea-pike*, is an allied species, frequenting the British shores and stretching into the Arctic regions. Some of this kind have been known to attain the length of eight feet, and to bite very severely; hence they may be considered as the sharks of northern seas. To this family belongs the most common of the flying-fish, though, as already stated, it is not the only one which deserves the title. The *exocœtus* is at once distinguished from the rest of the family by the immense size of its pectoral fins, by the impulse of which upon the water it is enabled to rise into the air; but it can scarcely be said to *fly*, since it is unable to do more, without again dipping into the water, than partially to sustain itself, and to direct the movement to which the impetus was given at the moment of quitting the water. Nevertheless, the common flying-fish can leap more than two hundred yards in distance, and upwards of twenty feet in height. They are not unfrequently found upon the decks of large vessels, across which they had endeavoured to pass. This power appears to be conferred upon them to enable them to escape from the pursuit of the Coryphæna; but, in avoiding one enemy, they put themselves in the way of others, for voracious birds watch for them and seize them as they rise into the air. They furnish an excellent article of food, and are very abundant in the neighbourhood of some tropical islands; individuals have occasionally appeared as stragglers on our own coasts.

3. The Siluridæ are distinguished from all the rest of the order by the want of true scales; having only a naked skin, or large bony plates. The fishes of the genus *Silurus* inhabit the rivers of warm countries; they have a strong spine in front of the dorsal fin, which can be laid flat on the shoulder, or perpendicularly erected so as to become a formidable weapon; and the ragged wounds inflicted by it are reputed (but probably erroneously) to be poisonous. One species, belonging to the sub-genus *Malapterurus*, an inhabitant of the Nile and of the rivers of Central Africa, has electric properties, similar to those of the torpedo and gymnotus.

4. The fishes of the order Salmonidæ, known as *salmons* and *trouts*, are very extensively, indeed almost universally, diffused over the globe, some of them being confined to fresh water, and others passing a part of their lives in the sea, but resorting to rivers to deposit their eggs. They are distinguished by the fatty deposition in the dorsal fin, from part of which the spines often disappear. All of this family are clouded with dusky patches when young, as occurs in all the species of Cats. Many remain permanently spotted. The flesh of most of them is esteemed as food. The *salmon* inhabits the seas of comparatively cold regions, ascending the rivers for the purpose of spawning at seasons varying with the climate. The efforts which they make to overcome difficulties in the ascent are very great; they will not only swim against powerful streams, but *will leap up cascades* of considerable elevation, and find *their way to the brooks* and small lakes of lofty mountains. They return to the sea after this ope accomplished, and are followed by the young from the eggs they have deposited. These, turn, ascend the rivers for the same purpose, understood to resort to those in which they w duced. The *trout* appears to vary much in colour, according to the climate and other cond its residence, so that it is difficult to distinguish from mere varieties.

Salmon.

5. The Clupeidæ, or *Herring* tribe, is one most important families in the whole class, amount of food it supplies to man. The fishes ing to it resemble the Salmonidæ in many ch but differ in having no fatty matter in the do They chiefly inhabit the seas of the tempera The *herring*, which periodically visits our sh such immense shoals, was formerly supposed to from Arctic seas; but this is now ascertained mistake, the fish being almost unknown there, a appearing on the southern coast of Britain be northern. The fact is rather that the herring, mackerel and many other fish, usually lives in ocean, and resorts to the nearest coast to de spawn. There are many well-known species, but little from the herring, which frequent localities. Thus, the *pilchard* is caught espe the coast of Cornwall and other shores to th ward of those on which the herring most abou *sardine* is taken on the west coast of France a Mediterranean, where the herring never appe *sprat*, *white-bait*, *shad*, and other British specie to the same family; as does also the *anchovy*, w for its rich and peculiar flavour, which is abu the Mediterranean. Other species inhabit t rican, African, and Indian seas and rivers, but less abundant than those already mentioned.

Order III.—Malacopterygii Sub-Brachiati.

The soft-rayed Fishes, which have the ven brought forwards beneath, or even in advanc pectoral, are divided into three families, one of equally important to man with the last, if not This is,

1. Gadidæ, the *Cod* tribe. The fishes of th are easily known by the softness of all their by having the ventrals inserted under the thr pointed. The greater number live in cold or t seas, and furnish a most important article of fo flesh being wholesome, easy of digestion, and a to the palate, and their numbers (owing to the ordinary reproductive power) extremely abund *cod* is nearly the largest of the family, but is surpassed by the *ling*, which is commonly fr to four feet long: both these are especially val their excellence when salted. The *haddock* is species, nearly allied to the cod; for eating in state, it is perhaps the most delicate of the who Many other species are useful to man, occ large numbers in particular localities. Such *whiting*, the *coal-fish*, the *pollock*, the *hauk* (some species frequent high southern latitu *burbot* (which ascends rivers), the *rockling*, a others. Besides their use as food, these fish able on account of the oil obtained from th livers, which is very serviceable in the arts.

2. The second family is that of Pleuronec *Flat-fish* or *Flounder* tribe. The form of the peculiar, not only for the extreme flattenin body, but for its deficiency in symmetry. Th surfaces—one of which (in the ordinary posit fish during life) is above, and the other belo reality the two *sides* of the fish, differing in seve tant respects. Both the eyes are placed on t side; and its colour is usually much deeper other. The body, from the head backwards, p little of the same peculiarity. The two sid mouth are not equal, and the pectoral fins On the other hand, the dorsal fin, which runs of the lateral edges, corresponds with the anal,

Order VI.—Plectognathi.

This order, the last of the osseous Fishes, approaches the cartilaginous in many points of its organisation; principally, however, in the slow ossification of the skeleton, and the imperfect structure of the mouth. They derive their name, as already stated, from the union of the upper jaw to the skull; so that its motion is obtained, not from a distinct joint, but by the mere flexibility of the half-ossified cartilages. The gill-lid is concealed under the thick skin, with only a small opening; the ribs are scarcely developed; and there are no true ventral fins. This order contains two families.

1. The Gymnodontes, or Naked-Toothed Fishes, are distinguished by having the jaws covered with a substance resembling ivory, arranged in small plates (which are reproduced as soon as destroyed by use), and really representing united teeth. They live on crustacea and sea-weed, and their flesh is not palatable. Some species are reputed to be poisonous, at least at particular seasons. The most remarkable species of this family are the spinous globe-fishes, *diodon* and *tetraodon* (their technical names being derived from the apparent division of their jaws into two and four tooth-like pieces respectively), which have the power of blowing themselves up like balloons, by filling with air a large sac which nearly surrounds the abdomen. When thus inflated, they roll over with the belly upwards, and lose all power of directing their course; but they are remarkably defended by spines over their whole surface, which are erected as they are inflated. They are mostly inhabitants of warm seas, but a specimen is occasionally drifted to our coasts. The *sun-fish* has a body of somewhat similar form, but incapable of inflation; the tail is so short that it looks like the anterior half of a fish cut in two in the middle. Some species attain an immense size. One which is occasionally taken on the British coast has been known to weigh 300 lbs., and others are much larger.

2. The second family, Sclerodermi, contains fishes which are remarkable for their very hard and granulated skins. They have a prolonged muzzle, with distinct teeth. Their skin is covered with scales in some species, and in others very rough, like a file, whence they are commonly termed *file-fishes*. They are principally inhabitants of warm seas, living near rocks or on the surface of the water, their brilliant colours sparkling in the sunshine like those of the Chætodons.

DIVISION II.—CHONDROPTERYGII OR CARTILAGINOUS FISHES.

The skeleton of these fishes is not entirely devoid of calcareous matter, but this is disposed in separate grains, and does not form fibres or plates. Hence the hardest portions of the framework remain quite flexible. The freedom of motion of the spinal column, which is characteristic of fishes in general, is here still further increased, in many species at least, by the continuation of the sac containing gelatinous matter (which in the osseous fishes was simply interposed between each pair of vertebræ) through the whole column, the bodies of the vertebræ being pierced in the centre so as to form a continuous tube. This division contains two subordinate groups: in the first, the gills are attached by one edge only, hanging in fringes as in the osseous fishes; in the second, they are so attached to the skin by the second edges, that the water cannot escape from their intervals except by holes in the surface. Accordingly, instead of having a single pair of large apertures, with a valve-like cover, or *operculum*, behind the head, they have as many apertures on each side as there are arches of gills. The first series contains but one order, and the second the other two.

Order VII.—Chondropterygii Branchiis Liberis.

This order contains only one family, the Sturiones, or *Sturgeon* tribe. In many of its characters, as well as in the disposition of the gills, it is intermediate between the Osseous Fishes and the Shark tribe, which may be

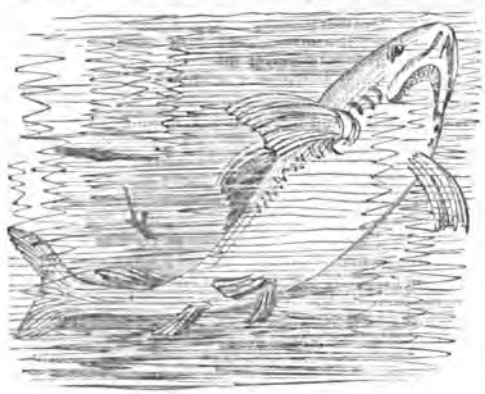
regarded as the types of the Cartilaginous division. Sturgeons are chiefly river fish, and from their large size, vast numbers, and the quantity of food and other important products they afford, are extremely valuable to man. The common sturgeon of the British shores is about six feet long, and its flesh is somewhat like veal. The rivers falling into the Black and Caspian Seas, however, produce several other species, of which the largest not unfrequently attains the length of fifteen feet, one individual being recorded as having weighed 3000 lbs. The roe of the sturgeon furnishes the caviar so much esteemed in Russia; and its air-bladder furnishes isinglass.

The section of CHONDROPTERYGII BRANCHIIS FIXIS is divided into two orders, the first having teeth, and the second having the mouth formed into a sucker.

Order VIII.—Selachii.

This order only comprises one family, that of *Sharks* and *Rays*. A great metamorphosis here takes place in the condition of the bones of the mouth, those which are commonly termed the jaws, in which the teeth are fixed, being very different in position and character in osseous fishes, and the true jawbones not being here developed. This tribe is distinguished from other fishes by many peculiarities: in several members of it the young are produced alive, the eggs being hatched within the body of the parent; and in others the eggs are enclosed in a peculiar horny casing, which has often long tendril-like appendages, that coil round and attach them to other bodies. This is the case with the eggs of the common *dog-fish* of our coast, vulgarly known as *sea-purses*. The Sharks much resemble ordinary fishes in their form, having the gill-openings on the sides of the neck, and the the eyes on the sides of the head, in both of which respects the Rays differ from them. The *dog-fish* of the British coasts differs but slightly from the true sharks, and is, in its way, equally voracious.

The *white shark* is the most celebrated species of the tribe, being, from its size and voracity, the terror of mariners in the seas it inhabits. It frequents warm



White Shark.

latitudes, but has occasionally visited the British shores. It has been known to attain a length of thirty feet, and the opening of the jaws in the largest individuals is sufficient to admit with ease the body of a man. The mouth is placed on the under surface of the head, from which circumstance the fish cannot bite whilst in the act of swimming forwards, so that a dexterous person has been known to defend himself from its attack.

A remarkable genus allied to the Sharks is the *zygæna*, or *hammer-headed shark*, so named from the projection of the head at each side in the form of a double-headed hammer, with an eye in the middle of *each extremity*. The *pristis*, or saw-fish, is another *interesting genus*. Its general form and character is like that of the sharks, but the snout is ext the blade of a sword, with strong and cutting spines on both edges. With this formidal the fish, which sometimes attains the leng twelve to fifteen feet, will attack the largest inflict dreadful wounds. To the shark tribe the *angel fish* of our own coasts, which forms to the rays in its general structure and ha eyes are situated on the back or upper sur head; the body is broad and flattened horizo the pectoral fins widely expanded. It comm to the length of seven or eight feet; its appear belies its name, being (according to our ideas one of the ugliest of fishes, but its flesh is by unpalatable.

The *Rays* are less numerous than the Sh abound rather in temperate than in tropical are characterised by the extreme horizontal of the body, in which, however, there is not (Pleuronectidæ) any want of lateral symmetry sides are expanded horizontally, and unite expanded and fleshy pectoral fins to form on ous surface. The eyes are placed on the back surface, whilst the mouth, nostrils, and gill are below. To this group belong the *rays* a *thornbacks*, and other species; but the most i of all is the *torpedo*, or electric ray, sometimes the Channel coast of England, but more ab the Mediterranean. The electric apparatus similar structure with that of the *gymnotus*, disposed in the space between the pectorals head and gills. The shocks given by this fish smart, are not so benumbing as those of the g their use in its economy are not apparent, as mal can obtain its prey without them. The fl rays is wholesome, and that of most species as food. The skin of some of them is employ arts for polishing, and, from that of others, sh made.

Order IX.—Cyclostomata.

The third order of the Cartilaginous Fishes, last of the class, is one which contains comp few species, and these exhibiting but a very gree of organisation. They take their name adaptation of the mouth to the purposes of suc its transformation into a round fleshy disk, ha oral opening in the centre, and the margin s by a ring composed of the cartilaginous jaw together. The spinal column loses its distinct into vertebræ, the space elsewhere occupied bodies being traversed from end to end by a cy membranous tube filled with a mucilaginous fl this, in the higher species, presents cartilagino at intervals, which are the rudiments of ve whilst, in the lower, there is no vestige of thes and the whole structure is reduced to the level of the Annelida. The pectoral as well as the fins are absent; and the skin is soft and muco scarcely a vestige of scales. This order contai single family. The *lampreys* are the most other fishes in their general organisation; they teeth within the ring, and with these they bodies of the animals to which they attach the There is a marine species two or three feet l other smaller ones which inhabit rivers. The or *hag* is destitute of eyes, and is altogether organisation than the lamprey; but the spec differs most in its general characters from th the class is the *amphioxus*, or lancelot. This small animal, about an inch long, sometimes fou ing under stones in pools left by the ebbing tid destitute of almost every one of the characte have been mentioned as peculiar to vertebra nuals; and, nevertheless, can scarcely be cla where else than with this family.

ZOOLOGY—(CONTINUED.)

SUB-KINGDOM—ARTICULATA.

: the Vertebrata we might pass, in descending the al scale, either to the Mollusca or the Articulata, of which exhibit some points of approximation them. In both we meet, as in the Vertebrata, very highly organised as well as very simply con- ted beings. In both we find animals much superior e lowest Vertebrata; and in both, also, we find es which are in many respects below the highest ata. It is the necessary consequence of a *natural* agement, which aims at grouping together the rent forms of living beings according to the type an on which they are constructed, that such should e case. Neither of these two sub-kingdoms can garded as in all respects superior to the other. high development of the locomotive power in the ulata strikingly contrasts with its usually slight sion by the Mollusca. On the other hand, the tive and nutritive systems in the Mollusca are h more complex, and attain a higher organisation; at the heart, for example, of the Tunicata is as rful in its action on the circulating fluid as that of highest Articulata. On the whole, however, the ulata should be regarded as ranking above the lusca in the animal scale, since it is in the *animal* rm that the former have the superiority.

he general character of the series has been already n as being the jointed or *articulated* character of skeleton or hard portion of the structure, and the ture of the whole body in this. Nothing can be nd in the Mollusca at all approaching in character to shell of a lobster or the horny case of the beetle. the peculiarity of the skeleton in the Articulata, it not merely encloses the body, but is prolonged the appendages for locomotion, where they exist; the portions of it which cover these are also jointed, the sake of conferring upon them the requisite bility. This structure is more apparent, however, me cases than in others. In the lowest animals is series, where there are no appendages for loco- on, and where all movements are effected by the itself, this is endowed with great flexibility, and whole envelope is so soft that the division into seg- s can scarcely be recognised. This is the case, xample, in the leech and earthworm. The articu- character is most apparent in the Centipede tribe, e the segments are all of nearly equal size, and e each possesses a short pair of legs, which are selves also articulated. But in the highest classes is sub-kingdom we again lose the appearance of division into segments, from an opposite cause— consolidation of several rings into one piece. In portion as the locomotive power is more intrusted e extremities, so does it become unnecessary that trunk should possess much flexibility; and in the e proportion does it become necessary that the portion of it from which arise the muscles of those extremities should be very firmly framed. Accordingly, the part of the body behind the head, which is called the *thorax*, and from which the legs and wings of Insects, and the principal walking legs of Crustacea, have their origin, very commonly appears as if composed of one piece, although it is really made up of three or more segments, each one of which gives origin to a pair of members.

The Articulata are almost invariably of small size; and the bulk of their bodies is made up, not by their digestive and nutritive apparatus, but by the muscles which move it. It is only in those which approach the Mollusca in the vegetative nature of their existence, that we find any considerable dimensions attained. As the Mollusca are an essentially aquatic group, so are the Articulata principally adapted to atmospheric respiration; and the most active among them can even quit the surface of the ground and mount up into the air. We find their respiratory apparatus constructed, therefore, upon an opposite plan. Instead of the blood being sent into external prolongations of the surface—the gills—to meet the air contained in the surrounding fluid, the air is introduced into the body to meet the blood, this being distributed on the sides of cavities or tubes into which it enters. In Insects these tubes have a very complex and beautiful distribution through the body.

The Articulata exhibit a peculiarity in the nervous system, which often enables the real character of doubtful animals to be distinguished. A double cord runs along the centre of the *lower* surface of the animal, studded with knots or *ganglia* at regular intervals, which are so many centres from which the nerves pass off to the different segments. The head, also, has its ganglia, in which the double cord terminates anteriorly. Where the members, however, are not uniformly distributed along the whole body, but are concentrated to one part, as in Insects, Arachnida, and the higher Crustacea, we observe a corresponding concentration of the ganglia in that region. The degree of this concentration indicates the elevation of the animal in the series.

The following classes must be arranged in the articulated series, though in some of them the characteristic structure is very indistinct:—

ANNELIDA, or *Worm* tribe. In these the body is prolonged, without any distinct appendages for locomotion. The habitation is usually aquatic, though sometimes terrestrial. The division into segments is not very distinct, the entire skin being soft.

MYRIAPODA, or *Centipede* tribe. These have also a prolonged body, but it is provided with legs; and the articulation of the covering both of the body and legs is very distinct.

INSECTS, which are distinguished in their perfect state by the possession of one or two pairs of wings; by the restriction of the legs, which are never more than six

in number, to the thorax; and by the division of the trunk into three portions, the head, thorax, and abdomen, which are usually very distinct from one another. They are also distinguished by their remarkable metamorphosis, commencing from a form which resembles that of the Annelida.

ARACHNIDA, the *Spider* and *Scorpion* tribe, which differ from insects in having the head and thorax united, in undergoing no metamorphosis, and in having eight or more legs.

CRUSTACEA, which have a hard envelope, principally composed of earthy matter, and which are adapted for aquatic respiration. Many of them have the form of insects; but their legs are never less than ten in number.

The foregoing constitute a tolerably regular series, into which we must also introduce the ENTOZOA, which seem to exhibit the characters of the Worm tribe in their most degraded condition, and the animals composing which are parasitic upon or within others; the ROTIFERA, or *Wheel-Animalcule* tribe, of which some approach the Polypifera and Polygastrica, whilst others approximate the Crustacea; and the CIRRHOPODA, or *Barnacle* tribe, which bear a strong general resemblance to the Mollusca, but unquestionably belong to this series.

CLASS VI.—INSECTS.

The class of Insects is perhaps the most interesting in the whole animal kingdom, both in regard to the number, variety, beauty, and complexity, of the different forms which it contains, the vast assemblages of individuals of the same species which not unfrequently make their appearance together, and their consequent importance in the economy of nature.

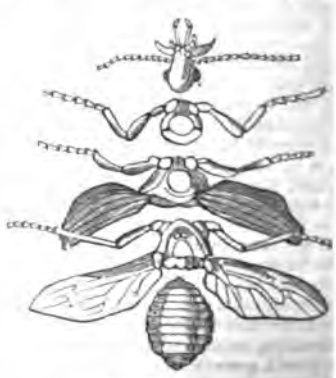
The true INSECTS are distinguished from the Crustacea by their peculiar apparatus for atmospheric respiration; from the Arachnida by having but six legs (eight being the number in that class), and by the division of the body into three parts; and from the Myriapoda by the limited number of legs and segments, the latter seldom exceeding thirteen. In the perfect Insect it is sometimes difficult to distinguish the division into segments; they may generally be seen, however, on the lower side of the body, especially on the abdomen. But in the larva or caterpillar state they are never obscure, and their number is very constant, being almost always thirteen, one forming the head. Of the twelve segments of the body, three in the perfect insect form the thorax, or division succeeding the head, whilst the remaining nine constitute the abdomen. It is more common for one or two segments to be apparently deficient (being consolidated with the rest), than for any increased number to be present.

The *metamorphosis*, or complete change of form, which may be seen in the greater number of insects during their development, has attracted much attention from the earliest ages to the present time. The *larva*, which afterwards changes to a beetle, a butterfly, or a wasp, bears no resemblance whatever to the perfect or *imago* form, and is in fact allied, in almost every particular of its conformation, to a class far beneath. Moreover, it has to go through an intermediate form—if any thing, still more remarkable—that of the *pupa* or *chrysalis*, in which there is an almost complete cessation of activity, but in which preparation is being made for the exit of the perfect insect at its final change. The alteration of the entire character of the animal is no less remarkable that its change of form. In the *larva* condition, its whole energies seem to be concentrated upon the nutritive functions; the voracity is extreme, and the increase in the weight of the body is very rapid; whilst, in the perfect insect, the body undergoes little increase of size, but it is provided with powers of active movement, and these are principally destined to enable it to seek its mate, for the purpose of propagating its race.

The *larva*, when it first emerges from the egg, bears but a very small proportion to its subsequent bulk. According to Lyonnet, the comparative we full-grown caterpillar of the goat-moth to t young one just crept out of the egg, is as 72 During its increase, it throws off its skin seve like the Crustacea. The larvæ in the differ vary extremely as to the degree of their dev in some orders they are extremely imperfect, possessing legs; whilst in others they corres the perfect insect in almost every particular presence of wings.

After attaining its full growth in the larva (the bulk of the body in this state often much that of the imago), the insect undergoes a ver able change, ceasing to take food, and appare all appearance of vitality. In this state it is t *pupa* or chrysalis. Many larvæ enclose them silken cocoon, or in some other kind of envelo undergoing this change; and remain in it d whole period of inactivity, which is sometim months in duration. Others bury themselv ground; and others, again, suspend themsel air. The pupæ of different orders of insects the larvæ, both in form and in degree of torp have the whole body enclosed in a horny cas vestige of members, and are totally inactiv when disturbed; whilst others present the gen of the perfect insect, but appear as if the body were separately bandaged, and laid in close a whilst others retain all their limbs free, and diminution in their locomotive powers or in t fite for food. These, indeed, can scarcely b pass into the pupa state at all, their condit only indicated by the gradual development of t This development is equally taking place be envelope of the pupæ that are enclosed and i

The perfect insect or imago, when it emer its pupa case, exhibits in all respects the *fo* is characteristic of the species, and, in genera also; few growing much after they have atta condition, and many scarcely eating at all. A mentioned, the twelve segments forming the b larva may still be recognised here, but ve changed in their character. The three ante are often soldered, as it were, together; for one strong sheath for that portion of the b which the wings and legs proceed, and th affords firm attachment for the powerful musc move these organs. Those which constitute men, however, retain much more of their aspect. The head is now quite distinct from and connected with it by a neck, which is narrow. From each of the segments of the pair of legs proceeds; and the second and thir give origin to a pair of wings each. Where, only one pair of these organs exists, they proc the second segment. The segments of the never show any vestige of legs. The accor diagram represents the chief parts of the perfe



Segments of Insect.

egments of the thorax are separated from to show the organs attached to them.
cial function of the perfect insect is the con- the species; and the wings enable it to seek id to obtain a situation fit for the deposition which are always laid in the neighbourhood : substances will supply the larvæ with nou- lthough it most commonly happens that the not feed upon them. Many insects, such *corm* moth and the *ephemera* or May-fly, die having fulfilled this object, to which they :y soon after their last change.

' extraordinary is the metamorphosis of in- y no means *unique*, as was formerly supposed: : of the tadpole into a frog, is an exact pa- ; for the tadpole is for the time a fish, re- iat class in its entire organisation, just as is for the time a worm. Moreover, we shall ee, in some of the lower classes, a change lly as remarkable. When the larva is very and the pupa inactive, so that its change to the perfect insect is very striking, the meta- is said to be *complete;* but if the larva is ıced, and the pupa differs little from it and erfect insect, the metamorphosis is termed

n their perfect state, are distinguished beyond iimals for their power of locomotion, and for on of their instinctive actions. In estimating r of locomotion, the space traversed is of pared with the length of the body; and thus iat, rapid as is the flight of many birds, that ects far surpasses it. The senses of insects ɔe acute. They have generally large eyes, fact, by the union of a great number of small ı several thousand; and although these are from their being directed at various angles er, a great range of vision is obtained. It is at insects possess the power of hearing, and ll; though no distinct organs for receiving essions have been satisfactorily determined. have a delicate sense of touch in some part , even where the general envelope is firm, questioned; and, from observations made ɔcial insects, such as bees and ants, there is elieve that they communicate with each other se.

:rent organs on the head of insects, furnish, rieties of conformation, important characters ation. It will, therefore, be necessary to ese in some detail. The most important , upon which, in primary subdivision ss is founded, are m the structure of ; in one large group hed with *mandibles* lapted for biting and whilst in the other, ed with a *haustellium* is, adapted for suc- ce the first group is NDIBULATA, and the AUSTELLATA. * side; B, under side; C, parts separated: *a a*, an- yes; *l* 1, upper lip; *m m*, mandibles; *m x*, maxillæ; ry palpi; *l* 2, labium; *l p*, labial palpi; *c* 2, chin or

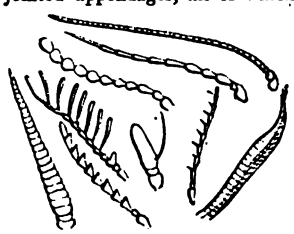
The two lateral pairs are the jaws; of which the upper pair is distinguished by the name of *mandibles*, and the lower by that of *maxillæ*. The mandibles are usually the largest, and are very powerful organs; sometimes they are provided with sharp or toothed edges, working against each other like those of a pair of scissors; and sometimes with hooked points, more formidable, for the size of the animal, than the teeth of the tiger. These are the principal organs by which the food, of whatever description, is usually obtained; but in the bees and wasps, of which some species are adapted to obtain their nourishment by suction, they are the instruments by which their curious edifices are built up. In a word, as has been well remarked, they supply the place of trowels, spades, pick-axes, saws, scissors, and knives, as necessity may require. The *maxillæ*, or under pair of jaws, are of similar construction, but usually smaller and less powerful. The pieces which are applied above and below to the spaces left between the jaws, are termed *lips;* the upper one being particularised as the *labrum*, and the lower one as the *labium*.

Various modifications of these parts are seen in the different orders of insects, but their existence may always be detected under some form or other. The most remarkable alteration in the structure of the mouth is that which we find in the Lepidoptera or Butterfly tribe. Instead of cutting jaws, we observe a tubular appendage or trunk, which is often of considerable length, and coiled spirally beneath the head, but capable of being unrolled when its point is required to descend into the corollæ of flowers. This tube is composed of two long narrow filaments, which are in fact the *maxillæ* excessively drawn out; these filaments are channelled on the sides at which they approach one another; and by the adhesion of the edges of these channels, which lock together by means of minute teeth, a complete tube is formed. In this mouth, therefore, all the parts except the maxillæ would seem at first sight to be wanting; but they may be detected by a careful examination, and the rudiments of the upper lip, of the mandibles, and of the lower lip, as well as of the *palpi* (organs to be presently described), may be distinctly demonstrated. In other instances, an entirely different modification of the same parts may be observed, which will be noticed in the proper place.

The head of the perfect insect is usually furnished with three pairs of jointed appendages, all of which are probably instruments of sensation. The first of these are termed *antennæ;* they are affixed to the sides of the head, and usually between the eyes and the mouth. The number of joints in them, and the forms they present, vary in the different tribes of insects, as also does their size, within very wide limits. Sometimes they are three or four times as long as the whole body, and sometimes they are scarcely to be perceived; sometimes they are simple thread-like organs, gradually tapering from the base to the point; sometimes they swell out towards the extremity; and often they possess side branches or appendages of various forms. These different characters are extremely useful in classification. The *palpi*, or feelers, are organs which are not dissimilar in general character, but are usually of much smaller size, consisting of seldom more than six joints; of these, one pair is attached to the *maxillæ*, and the other to the *labium*, and they are called *maxillary* and *labial palpi* respectively.



Variously formed Antennæ.

The uses of these organs are involved in some obscurity. There is good reason to believe that all of them are organs of touch; and this sense is probably some-

times most acute in the antennæ, and sometimes in the palpi. There is also reason to believe that the sense of hearing is in some way connected with the antennæ; and a curious modification of the joint at the base seems to be particularly appropriated to this function. It has also been thought that the antennæ minister to the sense of smell.

The *wings* of insects are the organs most peculiar to them; nothing at all analogous being developed in other articulated animals. They consist of a double layer of membrane, prolonged from the skin which covers the body, and partaking of its characters. This membrane is supported by a frame-work of harder structure, composed of ribs, which go by the name of *veins* or *nerves*. These terms must not be supposed to imply any analogy of structure with the organs they designate in higher animals; they are rather drawn from the analogous parts in the leaves of plants.

There is scarcely any organised substance upon which insects are not adapted to prey. In regard to the food of individual tribes of insects, it may here be stated generally, that some are purely carnivorous, devouring only prey which they have themselves killed. Others eat carrion, and even keep it until its decomposition is advanced. Others are herbivorous; some feeding only upon particular species of plants, whilst others are not restricted, but feed upon almost any vegetable substance. Others again are omnivorous, and will attack almost any thing that falls in their way. The excessive multiplication of insects, which would result from the enormous number of their eggs, and from their rapid growth, is prevented by the influence of other tribes of animals, as well as by the wars of their own tribes against each other. The destruction of the larvæ of some insects by those of others is often enormous, and far exceeds in proportion the diminution in their numbers effected by higher tribes. There are no classes of animals formed to exist on land, however, of which part do not derive a great proportion of their food from insects; and thus, if man does not interfere with the economy of nature, a balance is maintained, which is rarely disturbed. But if these higher tribes be destroyed (as, for example, if a rookery be dispersed), insects will then multiply inordinately, and will become a pest to the country.

Insects are distributed abundantly over all the portions of the globe yet trodden by man. Even in the coldest regions which he has yet explored, they present themselves to his notice during the brief summer; and no severity of the winter appears capable of destroying their vitality, although it reduces them to a state of complete torpidity. It is in tropical regions, however, that the largest and most brilliant species are usually found.

With these general remarks, we are now prepared to consider the principal subdivisions of this important class in more detail. These subdivisions are principally formed upon the character of the wings; since it is found that the structure of these organs affords a good general index of that of the body in general. But it cannot be trusted to alone. For, whilst certain orders may be included under the general designation *Aptera* or wingless, and another is termed *Diptera* or two-winged, we find wingless and two-winged insects in all the other orders.

Winged insects may be distributed amongst the eight following orders, of which the first four are Mandibulate, whilst the rest possess a mouth formed for suction, and are termed Haustellate.

1. Coleoptera (*Beetles*). In these the two anterior wings are converted into a horny or leathery substance, and enclose the posterior when folded.

2. Orthoptera (*Grasshopper, Cockroach*). In these the anterior pair of wings is composed of a substance more resembling membrane.

3. Neuroptera (*Dragon-Fly, White-Ant*). Both pairs of wings are membranous, and the nerves form a close network by their interlacement.

4. Hymenoptera (*Bee, Wasp, Saw-Fly*). Both pairs of wings are here also membranous; but the larger areas between them. The tail is poss sting.

5. Homoptera (*Cicada, Lantern-Fly*). In the four wings are of the same consistence, of what parchmenty; and, when folded, they inc angle like the roof of a house.

6. Hemiptera (*Bugs*). The anterior pair is horny or leathery, but generally tipped wi brane; both pairs are horizontal or but slightly

7. Lepidoptera (*Butterflies* and *Moths*). T four membranous wings, covered with minute

8. Diptera (*Gnat, Fly*). These have but t and are in many respects parallel to the H tera.

Besides these, there are some small orde mediate between the principal groups. Thus a order, Trichoptera, has been formed to include *worm-flies*, which are intermediate between tera and Neuroptera. The order Strepsipte comprehends a small group termed *wasp-fl* mediate between the Lepidoptera and Dipte

The Aphaniptera, the order to which the longs, are entirely *apterous* or wingless, and but undergo a metamorphosis, by which they alliance with the Diptera.

The Wingless Insects, which do not und metamorphosis, may be distributed into two 1. Parasita (*Louse*); and, 2. Thysanoura (*Spr Spring-tail*). These connect true Insects Myriapoda.

These orders will now be considered more i

Order I.—Coleoptera.

This order comprehends all insects which anterior pair of wings converted into wing-*elytra*, and which undergo a complete metam These wing-cases are of horny consistence, opaque, or nearly so. When expanded, the little or no use in flight; and, when closed, t along the back, in a strait line, which is c suture. The second pair of wings constitute organs of flight; they are of large size, and branous texture; and, when unemployed, they up in several transverse folds, and are entirely c beneath the elytra. The mouth is formed for mas and possesses two horny mandibles. The head vided with two antennæ, of variable form, and the number of joints is usually eleven; these ofte considerably in the two sexes. The eyes are la protuberant, especially in the carnivorous spec in those, the slowness of whose habits makes th quick powers of sight for the purpose of avoidi enemies.

The body exhibits a well-marked division int and abdomen. The former consists, as usual, segments; but the first of these is so largely de at the expense of the rest, as to appear almost stitute the thorax in itself. The abdomen usu sists of only six or seven segments; the rema the nine which properly form this part being lidated in the last.

Although the characters already mentioned a cable to by far the greatest number of insects inc this order, nearly all of them are subject to ex Thus, there are some species in which the flight are altogether wanting, as in the female of worm; others which have elytra, but no wings again, in which the elytra adhere together a suture; others, in which they overlap; others, they do not meet; and others, in which the v longitudinally folded. It is well for the stud aware that such exceptions exist in almost ev natural group, however definite its characters t rally be. In none of these instances is there tion as to more than one or two of the charac remainder conform to the usual type. The versal is that of the metamorphosis, which, b plete, distinguishes this order from others ap

ucture of the mouth or in the character of

e are worm-like in their aspect; the head is ny, and the rest of the body soft. There is pair of short jointed legs attached to each first segments, representing those of the ct. Those which possess legs are usually heir habits; but there are others which, tired life, and being born in the midst of (such as the nut weevil), are destitute of larvæ of the carnivorous species have in most robust legs; and in some of the her- pecies these are replaced by fleshy pro- r pro-legs. A pair of these generally exists

segment of the abdomen. Previously to its change, the larva often forms a case for s of earth or chips of wood, united by silken glucy matter. The *pupa* or chrysalis is metimes even for years, and takes no nour- ut the form of the future beetle is plainly the different parts being encased in distinct

much difficulty in forming a simple natural n of this immense tribe, on account of the er of distinct species it includes, and their eral resemblance to one another. Hence it ecessary to resort to characters of great as the groundwork of the system; and it happens that, by the adoption of such a plan, ch are in reality closely allied in general are placed in different groups, and others are gether which are generally dissimilar. No em has yet been proposed, however, than treille, who took as the basis of his classifi- number of joints in the *tarsi*, or divisions of e thus formed the four following sections:—

AMERA (or five-parted), in which the tarsi eet are five-jointed, the fourth being of ordi-

TOMERA (or differently-parted), in which the or tarsi are five-jointed, and the two poste- pointed.

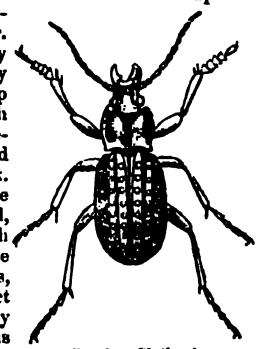
AMERA (or four parted), in which all the tarsi distinct joints. It has lately been observed, hat the fifth joint exists in these, although minute, and concealed in one of the others.

ERA (or three-parted), in which only three ized joints exist in the tarsi—a fourth of however, being also present. Hence these ections may be more correctly denominated tramera and Pseudo-Trimera.

these sections contains several families, of most important will now be noticed.

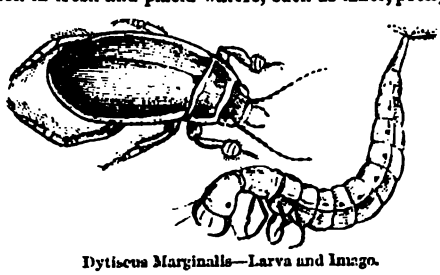
I. PENTAMERA.—1. The first family of this section is composed of Beetles exclusively carnivorous, hunting after and devouring other insects, and carnivorous even in the larva state. These *Carnivora* are characterised by the possession of six palpi, and by the termination of the jaws in a sort of claw or hook. Some of them are aquatic; others terrestrial. In many species there are no wings under the elytra. The terrestrial carnivora have legs fit only for running; their body is elongated, and their eyes are prominent.

To this division belongs the tribe of *Carabidæ*, which is of very great extent, above two thousand species having been brought together by a single collector. Their bodies are of very firm consistence, whereby they are enabled to creep under stones, and through fissures, and are also prevented from being injured by the insects they attack. They prowl about on the surface of the ground, under stones, &c., beneath the bark of trees, or in the moss growing at their roots, in search of their insect prey, which principally consists of the herbivorous species. Some of them are nocturnal in their habits, feeding upon Cockchafers and other species of herbivorous beetles that fly abroad by night. The habits of the family are not exclusively carnivorous, however, for some species generally found in corn-fields are clearly ascertained to feed upon growing grain. Many larger species of this tribe are provided with a very curious means of defence; being enabled to exhale a very fœtid odour, and to discharge from the abdomen, to a considerable distance, an acrid fluid capable of producing considerable irritation. In the *brachinus*, this fluid is so highly volatile, that, immediately on coming in contact with the air, it becomes a bluish vapour of very pungent scent, and makes a sort of explosion; hence the species possessed of this power have been termed Bombardier Beetles. They mostly live in societies.



Carabus Clathratus.

The *aquatic* Carnivora form a tribe far less numerous than the terrestrial species, and are characterised by the peculiar modification of the legs, which adapts them for swimming, these members being flattened and fringed with bristles, so as to serve as oars. They pass their larva and perfect states in water; quitting it, however, in order to undergo their metamorphosis into pupæ. The larvæ have the body long and narrow, with a strong head armed with powerful mandibles, and they are of very active carnivorous habits. They breathe by organs adapted for aquatic respiration, but the perfect insect can only breathe air, and it is obliged to come to the surface occasionally for that purpose. The *dytiscus*, the principal genus of this tribe, is common in fresh and placid waters, such as lakes, pools, or



Dytiscus Marginalis—Larva and Imago.

ditches. Its larva feeds upon other aquatic larvæ, such as those of dragon-flies, gnats, &c., and moves quickly through the water, striking it by its expanded tail. The pupæ may be found buried in the adjoining banks.

2. The next family is that of BRACHELYTRA, which possess but four palpi, and are distinguished, as their name imports, by the shortness of the wing-cases. The family consists of only one genus, *Staphylinus*, of which one of the largest species is known by the name of devil's coach-horse, and is frequently to be seen running about garden walks. These insects run and fly with equal agility. They are very voracious, but do not feed upon living prey, deriving their nutriment from dead and decaying animal matters, especially fungi, &c., in which they chiefly reside. They are also found in profusion under heaps of putrescent plants. They all possess the faculty of emitting a powerful odour, which seems to serve as a means of defence; and this is, in some instances, of peculiarly fœtid character. The larvæ feed on the same substances, and frequent the same situations, as the perfect insect. This group leads, in many respects, towards the Earwig tribe, with which the next order commences.

3. The family SERRICORNES is distinguished by the toothed or serrated form of the antennæ. Like the last, it possesses four palpi; but the elytra completely cover the body. Some of this family, having the body of solid consistence and oval in form, have the head buried, as it were, in the thorax, which advances on its two sides nearly as far as the mouth. In this way are formed the *Buprestis*, distinguished for the splendour of its colours, many of its species having spots of golden hue upon an emerald ground, whilst in others azure glitters upon the gold. These brilliant species belong to tropical climates, which these insects appear especially formed to inhabit, our native species flying with the greatest activity in warm weather. They live among trees; and if an effort be made to seize them, they counterfeit death, and fall to the ground. The beetles belonging to the allied genus *Elater* are commonly called skip-jacks; for, when laid on their backs, being unable to raise themselves on account of the shortness of their feet, they spring perpendicularly in the air, so as to alight upon their feet. This is effected by a violent backward blow of the head against the surface on which they are lying. The larva of an English species is known to the farmer as the wire-worm, which does much injury by devouring the roots of the corn. A species of elater inhabiting the West Indies and South America, has two brilliantly luminous spots upon the front of the thorax; and a portion of its abdomen which is uncovered during flight is also illuminated.

Another interesting genus of this family is the *Lampyris*, to which belong the glow-worm of this country, and some of the fire-flies of warmer regions. The body of these insects is very soft, especially the abdomen; and it is from the two or three last segments of this part of the body, that the phosphorescent light for which they are so remarkable, is emitted. Its intensity is evidently dependent in a great degree upon the state of the animal; if the insect be irritated it is increased, but if its powers are depressed or exhausted it is lessened. It seems to be sometimes withdrawn simply at the will of the animal. In the glow-worm (*L. noctiluca*) it is only the female that is luminous; and she is destitute of wings and elytra, which the male possesses. They are only active by night; and as the male is known to be attracted, like moths, by lights in houses, it is probable that the phosphorescence of the female is given for the purpose of signalising her position to him. In most of the tropical species, both sexes are furnished with wings.

4. The next family of Pentamerous Coleoptera is that of CLAVICORNES, characterised by the club-shaped form of the extremities of the antennæ. These are partly terrestrial and partly aquatic; they feed for the most part on animal matter, at least in the larva state. The terrestrial ones seem to prefer substances which are in a state of decay; they creep slowly, and are mostly of a dark colour—black or bronzed. One of the most interesting genera is the *Necrophorus*, or burying-beetle, so named from its habit of excavating the ground beneath the dead bodies of small quadrupeds, such as mice or moles; when they have interred the they deposit their eggs in it, and the larvæ whe feed upon the flesh.

5. The PALPICORNES also possess antennæ wi like termination; but these are never longer, a shorter, than one of the pairs of palpi. Ne these are aquatic, and have their legs formed ming. The most remarkable genus is the *Hydr* which a large species, *H. piceus*, an inch and a oval, of a brown-black colour, and highly p common in the ponds and ditches of this co swims and flies well, but walks badly. The laid in a sort of cocoon spun by the female with a gummy matter which is impervious to on which it floats. The larvæ, which have a body, with six feet, the head armed with str dibles, are very voracious, feeding upon tad the young fry in fish-ponds, and upon small f Mollusca.

6. The last family of the Pentamerous s LAMELLICORNES, is of very great extent, and most striking of the whole Beetle tribe, in the size of the body, and the variety in the f head and thorax in the different sexes; and in those species which in their perfect state vegetable substances, in respect to the brilli metallic colours with which they are orname the majority of the other species, which sol composing vegetable matter, are of an unifo or black colour; though some are not infer liancy to the preceding. All have wings, and but slowly along the ground. None of them a Their food consists of dung, manure, tan, a larly (in some species) of the roots of whence these insects, especially in their l often occasion great loss to the cultivator. receives its name from the peculiar confo the antennæ, which terminate in a mass for three last joints; these are flattened into pl mellæ; and sometimes arranged like a fan or of a book, sometimes in the manner of a sometimes enclosing each other. The famil buted into two principal sections, the *Scarab Lucani*.

Of the *Scarabæi*, one subdivision, including beetle of the Egyptians, feed principally upo crements of various animals, and they enclose their eggs in balls of the same (whence they have been called Pilularii), which they roll along with their hind feet (several often being in company), until they reach the hole in which they are to be deposited. A most remarkably formed species is the *dynastes hercules*, a native of Brazil, which attains the length of five inches, and of which the male possesses an enormous horn projecting from the head, which is opposed by a corr

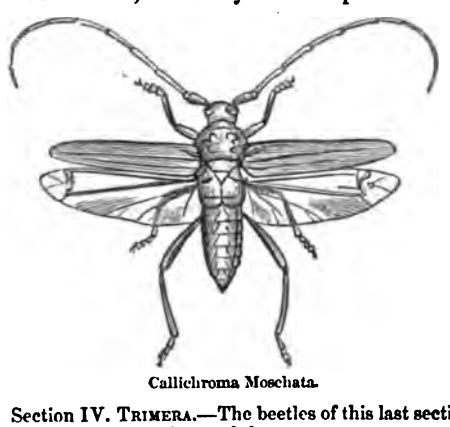
ily *Trachelides* the head is triangular or , and carried on a kind of neck, which from the thorax. The body is soft, the flexible, and sometimes very short. The in the perfect state upon different vege- ıring the leaves or sucking the honey of Many, when seized, depress the head and feet, as if they were dead. Their colours ·y brilliant. This is well seen in the *can- oria* or blistering-fly, which is of a shining ic hue; this insect is most abundant in ›pears about midsummer in France, and is bundantly on the ash and lilac, of which it ² leaves. Its larva lives in the earth, and ıe roots of vegetables.

I. Tetramera.—All the insects of this sec- vise vegetable-feeders. The perfect insect ›n the flowers and leaves of plants; the ten produced in their interior; and, when in the midst of their food, their legs are ery imperfect. Very often the true legs ıtirely absent, and their place supplied by les. The first family, that of Rhyncophoræ, *l* tribe, is distinguished by the prolongation or part of the head into a kind of muzzle. · of species in this family is very great; have been reckoned. Many of them are structive; especially the *calandra grana-* -weevil, which commits great havoc in To this tribe belongs one of the most all beetles, the *curculio imperialis*, well e diamond beetle, a native of South Ame- rica, in some parts of which it abounds. There are small species belonging to our own climate, which are scarcely less brilliant when magnified in a good light.

The second family of the Tetramerous Coleoptera has received the name of Xylophagi (Wood-eaters) on account of the peculiar habits of the beetles composing it. They usually live in wood, which their larvæ pierce in every direction; and, when abundant in forests, especially those of pines and firs, they destroy the trees in a few years, and sometimes in enormous numbers. They are destitute of the prolonged muzzle of the last order, and have short antennæ, thickened towards the tips. One of the most important species is the *bostrichus typographus*, so named from the figure of its burrows, which has at different times ravaged the forests of Germany. It devours the soft wood beneath the bark, which is most essential to the vegetative processes, both in the larva and perfect states, and thus causes the death of the tree. It was reckoned that a million and a half of pines were killed by this species alone in the Hartz forest, in 1783; and that as many as 80,000 insects were ordinarily engaged in the destruction of each tree.

The beetles of the family *Longicornes* are distinguished by the great development of the antennæ, which are always at least as long as the body, and often longer. The larvæ mostly reside in the interior of trees or under the bark, and are destitute of feet, or have them very small. They are furnished with robust mandibles, and do much injury to trees, especially those of large size, by burrowing deeply into them. They are vegetable-feeders in their perfect state also, and do great injury to plants, some attacking the leaves and others the roots. Many of them produce a slight creaking sound, by the friction of the joint which unites the thorax to the abdomen. Many of these are brilliantly coloured, especially the tropical species. Some of them are remarkable for exhaling an agreeable musky odour. This is the case with an English species, the *callichroma moschata*, which is about an inch long, entirely green or shaded with blue, and is very common upon willows.



Callichroma Moschata.

Section IV. Trimera.—The beetles of this last section are mostly of small size, and they are not very common. Their habits are various, a portion feeding upon fungi, and the remainder chiefly upon aphides. To the latter section belongs the genus *coccinella*, of which several species are known in this country under the name of lady-birds or lady-cows. They sometimes appear in great profusion, and have created much alarm. It is erroneous to suppose, however, that they do any injury to vegetation; for, on the contrary, they are of great benefit to plants by feeding on the aphides which infest them; and this they do both in the larva and perfect states.

Order II.—Orthoptera.

The order Orthoptera comprehends all insects that have the mouth armed with jaws fitted for mastication, and two pairs of wings; of which the anterior encase

the others, the posterior being membranous, and folding longitudinally during repose. In many respects they resemble the Coleoptera; and they are closely connected with that order by the Forficulidæ, or *Earwig* tribe, which partake of the characters of both. But they differ from the Beetles in the softer covering of their bodies; in the partially membranous character of the anterior pair of wings, which seem intermediate between the horny elytra of Beetles and the membranous wings of other insects, and which do not meet along the back when closed; and in the fan like manner in which the posterior wings are folded up beneath them, which is permitted by the straight direction of their veins. They differ also in their metamorphosis; for, whilst that of the Beetles is complete, that of the Orthoptera is only partially so; for the larva and pupa closely resemble the perfect insect in form, walking and feeding in the same manner, and differing in but little else than the absence of the wings and wing-covers, which are gradually developed in the latter.

This order comprises numerous well-known insects, often of large size and splendid colours; such as grasshoppers, locusts, walking-leaves, as well as cockroaches and earwigs. Some of the largest of known insects belong to it; a few species attaining a length of eight or nine inches, and an equal expansion of wings. Comparatively few of this order are inhabitants of temperate regions; it attains by far its greatest development, both in number, size, and colour, between the tropics. All the known Orthoptera are terrestrial, both in their perfect and two previous states. Some are purely carnivorous, and others are adapted to a mixed diet—the Cockroaches, for example, being capable of feeding on almost any organised matter, whilst the great majority feed upon plants. Hence, from their large size, and the quantity which each individual can devour, they are among the most destructive of all the insect tribes, when they appear in large numbers. This is particularly the case with the locusts in warm countries, the ravages of which not unfrequently cause famine and pestilence, both among men and beasts.

The Orthoptera are divided into two principal families. In the first, that of Cursoria, the legs are all alike, and adapted for running. They have generally the wing-covers and wings resting horizontally on the body. In the second, the *Saltatoria*, the thighs of the hind legs are much larger than the rest, by which they obtain great powers of leaping. In some of these, the wings meet at an angle when folded, like the two sides of a roof. The males have the power of making a sharp creaking noise, which is very loud in some species.

1. The Cursoria contain three well-known forms—the *Earwig*, *Cockroach*, and *Mantis*. Of these, the first approaches more closely than the rest to the Coleoptera; but have a peculiar character of their own in the forceps with which the posterior part of the body is provided; these are used as weapons of offence and defence. The *Blattæ*, or Cockroaches, are intermediate between them and other Orthoptera. These well-known insects are now pretty generally diffused over temperate climates, although most of the species are believed to have been originally natives of tropical regions. Their wings are small in proportion to the weight of their bodies; and in cold climates are seldom enough developed to lift them from the ground. The females are generally almost destitute of these organs.

The Mantidæ are purely carnivorous insects, of which none are natives of this country. They differ much from the Blattæ in the form of the body; which, instead of being flattened and oval, is narrow and elongated. The first pair of legs is enormously enlarged, and forms a very powerful organ of attack. They frequent trees and plants; and the forms and colours of their wings and bodies are often so adapted to those of the leaves and twigs which surround them, as to give them remarkable power of eluding observation. Hence these have been called walking-leaves. One species, the *mantis religiosa*, is regarded by the natives of the countries it inhabits with superstitious reverence, on account of its occasionally assuming the a prayer. This is, however, the position in wh in wait for its prey; the front of the thorax vated, and the two fore-legs held up toget pair of arms, prepared to seize any animal fall within their reach. They are extremely insects; and, if kept together without food, the victor devouring its conquered adversary.

Mantis Religiosa.

2. The family Saltatoria consists of numerou allied to the well-known *Crickets*, *Grasshoppers* &c. Besides the peculiarities already mentio are remarkable for the deposition of their eg ground, which is generally accomplished by m long horny ovipositor. The mode in which t is produced varies in different species.

The first division of the Saltatoria, termed includes the species known as *Crickets*. T essentially inhabitants of the ground, in whic them burrow; few have any power of active fl greater number of them, like the common hous are nocturnal.

The next subdivision of the Saltatoria, the is distinguished by the roof-like position of covers, when they are closed; they also po long thread-like antennæ. This group co *Grasshoppers* and their allies, which, althoug a general resemblance to locusts, differ from the inferior robustness of the body and th and slenderness of the appendages.

The last section consists of the various migratory locusts, forming the tribe *Locustid* are formed for a more active life than the being able to leap much farther, and to sustai flight. Their powers of devastation, also, are for they are produced in vast numbers, and cieties, so as speedily to destroy the vegetat spot on which they have settled. Thence their flight in great swarms to adjoining dist so great is the number of which these swarm that it is not speaking figuratively to say th is darkened by their passage.

Order III.—Neuroptera.

The Neuroptera resemble the Coleoptera a tera in the structure of the mouth, but differ in the conformation of the wings. The anter as the posterior pair are here membranous parent. In both, the veins form a very bea minute network, subdividing and uniting a to divide the whole surface into a large numb which very much exceed in number those of of any other tribe of insects. The posterior usually as large as the superior, or sometimes larger; if narrower, they are generally long

The body of the insects of this tribe, whic the well-known Dragon-flies, May-flies, and White Ants or Termites, is generally soft destitute of any very hard tegumentary

mediate size, none exceeding in dimensions the

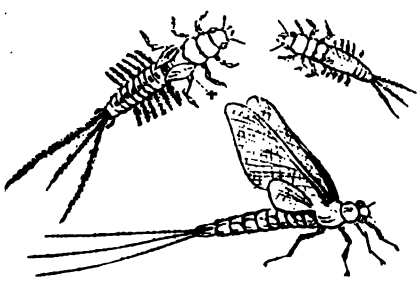
slenderness of some Hymenoptera and Coleoptera.
differ in the character of their metamorphosis as
ss in their adult structure; for in some the meta-
hosis is complete, the larva undergoing a marked
ge of form; in others there is not much difference,
t in the absence of wings, between the larva and
erfect insect. By these differences the order may
bdivided into two groups, in the first of which the
is active, whilst in the second it is quiescent, ex-
just before the assumption of the perfect state.
first of these groups may be farther divided into
which have terrestrial larvæ, such as the *Ter-
æ*, and those which are aquatic in their prepara-
states, such as the *Libellulidæ*, or Dragon-flies,
the *Ephemeræ*, or Day-flies. These pass the first
stages of their lives in water, respiring by means
culiar organs placed at the sides or extremity of
bdomen. In other respects their larvæ and pupæ
resemble the perfect insect. They creep out of
ater to undergo the final metamorphosis.

The Libellulidæ are well-known insects, being
distinguished by the slender form of their bodies,
varied colours, their large gauze-like wings, and
apidity of flight with which they pursue other in-
upon which they feed. They have a large head,
unded form, furnished at its sides with two very
eyes. The eggs are deposited upon aquatic plants,
the larvæ are produced in water, in which they
in until their last metamorphosis.

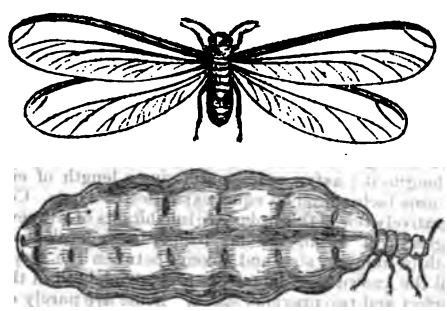
The Ephemeridæ derive their name from the short
tion of their lives in the perfect state. In the larva



Ephemera Vulgata—Larva, Pupa, and Imago.

tion they exist for two or three years; in this and
upa state they reside in the water, burrowing in
anks. In this condition, the abdomen is furnished
ch side with a row of plates, which appear to serve
ls for respiration, and also to act as paddles. The
differs from the larva in possessing rudiments of
, which are covered over with scales. At the
nt of their last change they quit the water, and
r, after casting their skin, in a new form; but, by
ular exception to what is elsewhere observed, they
to undergo another moult before they are fit for
agation. They generally appear at sunset in the
lays of summer and autumn, along the margin of
treams, &c., in which they have been developed.
take no food after their final change; and as the
agation of the race is then their only object, they
lmost as soon as it has been performed, often in a
ours after their exit from the water.

The Termitidæ, or White Ants, are terrestrial,
, and carnivorous or omnivorous, in all their
s. In several points of their structure they ap-
ch the Orthoptera; whilst in their habit of living
cieties they resemble the Hymenoptera. Unlike
ocial tribes among the former, however, the neuters
xless individuals in these communities officiate only
oldiers; and those which are here denominated
ers are in reality the larvæ, which closely resemble
erfect insect, except in the absence of wings. These
ts commit the most extraordinary ravages, the
numbers in each colony being almost incalculable, and
their voracity extreme. Their nests are sometimes
concealed below the surface of the earth, or in the in-
terior of trees, timbers, &c.; and through these they
bore galleries in such a manner, that, though the outer
surface is left untouched, they fall to pieces on the
slightest violence. Sometimes the nests are elevated to
several feet above the surface of the ground, and have
a pyramidal roof. When arrived at their perfect state,
the Termites quit their habitation, and fly abroad during
the evening or night in great numbers; they lose their
wings before the morning, and some of them, falling to
the ground, become the prey of birds, reptiles, &c.
The females, however, are sought by the workers, who
imprison them in royal chambers (as they have been



Queen in the winged state, and when filled with eggs.

termed) in the centre of the nest. The abdomen sub-
sequently attains an enormous size from the quantity
of eggs it contains; and these, when laid, are carefully
tended by the workers and defended by the soldiers.

4. Of the division of Neuroptera, in which a more
complete metamorphosis occurs, the family of Myrme-
leonidæ is one of the most remarkable. Their larvæ
have received, from their peculiar habits, the name of
ant-lions; they excavate conical pit-falls in fine sand,
and bury themselves at the bottom, their long mandibles
only appearing above the surface; and by these any
luckless insect that happens to fall down the hole is im-
mediately seized and killed.

The remaining families of this order need not be here
particularised.

Order IV.—Hymenoptera.

In the membranous character of their four wings,
the insects of this order resemble the Neuroptera; but
they cannot well be mistaken for them. The anterior
wings are usually much larger than the posterior; the
veins or nervures are much fewer in number than in
the Neuroptera, and do not form a close network by
their ramifications, as in that order. In some of the
minute species the wings are almost, or even entirely,
destitute of nerves. Another character furnished by
the wings consists in the connexion of the anterior and
posterior during flight, by means of a series of minute
hooks along the front edge of the latter, which catch the
hinder margin of the former, so as to produce one con-
tinuous margin on each side.

The principal character of this order, however, is
derived from the structure of the mouth; for, although
considered as mandibulate insects, the Hymenoptera
are much better fitted for imbibing their nourishment
by suction than for obtaining it by mastication, their
maxillæ being much prolonged and channelled, and
even uniting at their base into a tube, so as to form a
kind of proboscis. This is well seen in the bee. The
Hymenoptera are also peculiarly distinguished by a
prolongation of the last segment of the body in the
females, into an organ which is in one division of the
order a *sting*, and in the other an *ovipositor*, or instru-
ment for depositing the eggs, usually possessing the
power of boring a hollow for their reception.

The Hymenoptera are further remarkable for the

great development of their instinctive faculties and of their locomotive powers. It is in this order that we find the most remarkable examples of contrivance, and skilful adaptation of means to ends; but this adaptation results, it would appear, not from an exercise of *intelligence* on the part of the animals themselves (as in man and the higher Vertebrata), but from their blindly following out a plan laid down for them by the Almighty Designer. This inference may be deduced from the *invariability* of the operations performed by different individuals among the same species, so that a history of the life of one is equally applicable to all. The adjustment of instinctive actions to each other is nowhere more remarkable than in the case of the *social* insects, which are chiefly restricted to this order. The Bees, the Wasps, the Ants, the Saw-Flies, the Ichneumons, and the Gall-Flies, have attracted the attention of the observer of nature from the earliest period.

The insects of this order undergo a complete metamorphosis, the larvæ being amongst the most imperfect of those of any tribe. In the greater proportion of the order they are destitute of feet, and resemble little worms. These are dependent upon the instinctive care of the parent for support; which is either provided for by the deposition of the eggs in situations where the future grub will be certain of an ample supply of food, or by the active exertions of the parents, which convey to the young the food they have themselves collected for them, or by similar exertions on the part of a race destitute of peculiar sex (hence termed *neuters*), on whom this charge more especially devolves. When arrived at their full growth, and after undergoing several previous moultings, the larvæ are transformed into inactive pupæ, in which all the limbs of the future insect are visible, encased in distinct sheaths, and folded on the under surface of the thorax. During this part of their existence they take no food. In their perfect state, these insects, for the most part, take but little nourishment; and this almost exclusively consists of the nectar of flowers. Many of them, however, such as the Wasps, attack and destroy other insects; but these are often destined, not for their own support, but for the nourishment of the young. This order is of considerable extent, being inferior only to the Coleoptera; and it has been estimated as containing one-fourth of the whole insect population. It attains its greatest development in warm climates; for of the numerous species inhabiting this country, the greater part are of very small size. None of the species, however, attain any great dimensions; very few exceeding or attaining two inches in length, or three in the expansion of the wings. The duration of their lives, from the hatching of the egg to the final change, is believed never to exceed a year.

This order may be primarily divided into two sections, the TEREBRANTIA, in which the female is furnished with a saw or borer for the deposition of the eggs; and the ACULEATA, in which the abdomen of the females (and neuters) is armed with a sting connected with a poison reservoir. In the former, the antennæ vary considerably in the number of their joints; in the latter, there are always twelve in the female and thirteen in the male. The Terebrantia may be again divided into the PHYTIPHAGA, in which the larvæ feed upon vegetable matter; and the ENTOMOPHAGA, in which they in general feed parasitically upon living insects. The Aculeata are in like manner divided into the PREDONES, or predaceous tribes, which do not collect pollen, and in which the larvæ feed upon other insects stored up for them, or upon fluids provided by the neuters; and the MELLIFERA, in which the larvæ feed upon honey or pollen-paste stored up for them. The adult forms of all these are distinguished by certain technical peculiarities, which it would be tedious here to specify.

Section I. TEREBRANTIA.—The principal family of the Phytophagous Terebrantia is that of TENTHREDINIDÆ, or *Saw-Flies*, so named from the saw-like character and action of the ovipositor. With this instrument, they *make a succession* of small holes in the branches or *other parts of trees*, in each of which an egg and a drop of frothy fluid are discharged, the latter of which the hole.

The family of CYNIPIDÆ, or *Gall-Flies*, place count of its structure in the Entomophagous di the Terebrantia, is nearly allied in habits to som the last group. The ovipositor does not seem of boring a hole by itself; but, being armed w at its extremity, it can enlarge slits already for the deposition of its eggs. The fluid accu in the wounded parts forms excrescences or which are commonly termed *galls*, *nut-galls*, *apples*. Their form and solidity vary acco the parts of the plants which have been attac the species of the insect, of which each is n to a particular kind of plant.

Pimpla Manifestor engaged in oviposition.

The family of ICHNEUMONIDÆ may be rega peculiarly characteristic of the entomophagous The female deposits her eggs, by means of her pointed ovipositor, only in the bodies of other chiefly the larvæ of caterpillars, on which the may feed when hatched. Some of them have long ovipositor, which is used to insert the eggs bodies of caterpillars that live beneath the bar the crevices of trees; whilst those which have strument short, place their eggs in or upon the of caterpillars or pupæ to which they can obtain access. They do not confine themselves to thes tions, however; but employ for the same purp eggs or pupæ, still preferring the larvæ when t find them. The young Ichneumons, when hatc footless grubs, sometimes in considerable num the body of one larva, devour only the fatty which are not absolutely necessary to life; bu ready to undergo their metamorphosis, they pierce through the skin and escape, or else ki victim, and perform their changes within its bo

Section II. ACULEATA.—The Hymenoptera division may usually be distinguished from th brantia by the mode in which the abdomen is to the thorax. In the *Horers*, it is in general jointed to it—a structure which is evidently ne for providing the ovipositor with the requisite st whilst in the stinging Hymenoptera, it is usua nected by means of a peduncle or footstalk, v often, as in some of the Wasp tribe, of great len extremely slender. The predaceous division section contains several families, of which the portant only will be noticed in detail.

The CRABRONIDÆ, LARRIDÆ, BEMBECIDÆ, SP SCOLIDÆ, and MUTILLIDÆ, may all be considere one general description. They form a group may be termed that of *Fossores* or Diggers, fr peculiar habits; and they are commonly kn *Sand* and *Wood Wasps*. They are solitary in th of life, and consequently no neuters exist amo In general, the females excavate cells in the or in posts, timbers, &c., in which they deposit, with their eggs, various larvæ, or perfect ins

Hymenoptera belonging to the *mellifera* or ollecting division of the Aculeata, are known by ibar conformation of the hind feet, of which the nt is compressed and extended into the form of e plate, and provided on its inside with brush- s; these organs are employed for the purpose cting and carrying the pollen of flowers, which yed for the nourishment of the young. All of ects are commonly known by the name of Bees; tribe contains two families; in one of which all cies are solitary, and are of only two kinds— nd females; whilst the others mostly live in s, but are chiefly distinguished from the former in peculiarities in the structure of the mouth.

e solitary Bees which construct nests for them- there are many curious varieties, some of which r the names of Mason, Carpenter, and Uphol- Bees, from the material with which they work— agglutinating bits of sand or gravel, the next ing wood by means of their powerful jaws, and constructing their cells of portions of leaves. bits of all of these may be studied in detail with interest.

e social species there are two principal groups, mble-Bees, or Wild-Bees, and the Hive-Bees. mmon Humble-Bees of this country live in curious round habitations, in societies usually of fifty or at sometimes of 200 or 300 individuals.

Queen Bee.

Drone.

n the Hive-Bees that the arts of construction are d in the most elaborate degree. Their societies of but one female, com- ermed the queen, seve- ndred males, which are as drones, and about thousand working bees ers. It is by the latter the labours of the hive, struction of the combs, lection of food, both honey for the adults and or the larvæ, and the nourishment of the grubs, formed. The accompanying figures, selected from s sizes and species of these three orders. The

Neuter Bee.

wax of which the comb is constructed is secreted by the insects themselves, in little scales, which work out from between the segments of the abdomen. These are taken up and kneaded by the jaws, and applied in the proper place. The drones are killed at the end of the summer; but the queen and great part of the workers remain; and when, in the summer, they increase so much as to over-people the hive, colonies are sent forth with young queens, in search of another habitation.

Order V.—Homoptera.

The insects contained in this order present many curious anomalies of structure and habit, and depart more widely from the general type than is the case in almost any other division of the class. Hence it is difficult to assign any general characters which shall include them all. It is in the structure of the mouth that there is the greatest agreement. This is adapted for suction, the tongue being elongated and channelled into a gutter, and being surrounded by delicate lancet-like organs which pierce the tissues of plants. All the insects of this group subsist on vegetable juices; and some of them, from the amount of damage they commit, are very injurious to the cultivator. Some of the females are furnished with an ovipositor, provided with several toothed saws; and with this they make incisions into the leaves or stems of plants, into which they introduce their eggs. The anterior pair of wings is usually similar to the posterior in consistence, both being composed of a firm membrane: that which chiefly distinguishes the Homoptera, however, from the Heteroptera, is, that the substance of the anterior pair, whatever be its nature, is the same throughout, and that, when folded, they are roof-like.

This order may be divided, like the Coleoptera, into sections, according to the number of joints in the tarsi. These sections are only three in number; in the first, TRIMERA, the tarsi are three-jointed; in the second, DIMERA, they are but two-jointed; and in the third, MONOMERA, they have but one joint.

Section I. TRIMERA.—The three-jointed division of the Homoptera includes three families, of which two, the CICADIDÆ and FULGORIDÆ, are very interesting. The CICADIDÆ are the largest of the order; one species measuring between six and seven inches in the expanse of its wings. Their peculiar characteristic consists in their musical powers. By a peculiar apparatus situated beneath the abdomen, they are enabled to produce a continued sound, nearly monotonous, but of considerable power. In some species the sound is so loud and shrill, as to be heard at the distance of a mile.

The family of CERCOPIDÆ, also belonging to this section, consists of insects of small size, but which are remarkable for the grotesqueness of the forms which many of them assume; some inhabit this country, and are known by the name of cuckoo-spits and frog-hoppers; but the most singular species are confined to the tropics. The curious appendages represented in the

Bocydium Globulare. Bocydium Cruciatum.

accompanying figures of a Brazilian species, result from an extraordinary development of the first segment of the thorax. The insects of this family are often beautifully varied in their colours; they are constantly found amongst plants, and on trees, upon the juices of which they subsist, in all their stages. Of the best-known *species of this country*, the larva and pupa invest themselves with a frothy secretion, whence the vulgar name *is derived. Some* of this tribe are employed by certain

species of ants for the same purposes as th
having the power of supplying them with a
fluid.

The FULGORIDÆ are destitute of the power
ing sound, but are distinguished by a curious

Order VII.—Lepidoptera.

rder Lepidoptera, characterised, as formerly
y the downy covering of the wings (which is
d of minute scales, arranged with great regu-
on the membrane itself), contains some of the
utiful forms of the whole class, as well as some
great. The number of species it comprehends
ly as great as that of any other order except
ptera, and may probably rank as about one-
ne-sixth of the whole class.

insects of this order belong to the well-known
Butterflies and *Moths*; and there is so much
resemblance among them, that the difficulty of
g them is often considerable. The possession
upon the wings is not altogether peculiar to
r they are found on the wings and bodies of
ects. But it is only in these that the wings are
with such complete layers of them. The scales
ally of somewhat oval form, terminating at one
kind of stalk, by which they are attached
embrane of the wing; and on this they are
in rows, overlapping each other, like tiles on
they may be easily rubbed off with the finger;
bare membrane is left, which is then seen to
nd with the wings of other insects. The number
covering the wings of the silk-worm has been
d at about 400,000. It is entirely to the scales
colours of the wings are due; and sometimes
so brilliant, as to be almost painful to look
strong sunlight is reflected from the surface,
species the wings are partially, or even almost
destitute of scales.

pidoptera, in their perfect state, are formed to
rely upon fluid nutriment, which they suck up
s of a long trunk, which is usually coiled up
nder the head. This trunk is not an organ
r peculiar to them, however; for it is com-
out of the lower pair of jaws, or *maxillæ*, which
much prolonged: each is channelled on the
est the other, and furnished with very closely
along its whole edge; when the edges are
together, and the teeth lock into one another,
tube is formed by the junction of the channels
, and through this canal these beautiful insects
the juices of flowers. All the other parts of
h usually possessed by insects, may be detected
f the Lepidoptera, but in a different state of
ent. The antennæ are variable in size, and
composed of a great number of joints. The
usually large, and contain a considerable num-
ects.

urious phenomena of the metamorphosis are
d to our notice more remarkably, perhaps, in
r than in any other. All the beings commonly
Caterpillars, are the larvæ of Lepidoptera,
e produced from eggs of various forms and
markings (sometimes almost resembling Echini),
ave been deposited by the parent upon the

they then disengage the true feet, and retain-

ing hold with the pro-legs, thrust the body to its full length, and then recommence the same manœuvre. These are called Loopers or Geometers. Many of them resemble, in their forms and colours, as well as in their mode of standing fixed for a great length of time by their hind legs only to twigs, small pieces of stick.

The greater number of caterpillars are vegetable feeders, and are mostly confined to the leaves; and the correspondence between the development of the leaves

Caterpillar and Chrysalis of the Magpie Moth.

and flowers of plants on the one hand, with that of the caterpillars and butterflies which are respectively to feed upon them, cannot but strike every one as a beautiful instance of creative foresight. But there are some caterpillars adapted to feed on flowers (such as come forth early in the year); and others attack seeds, roots, and even the woody portion of the stem. Moreover, there are a few which live in this state upon animal matter, such as wool, hides, leather, and fat. Many can digest a considerable variety of alimentary materials; whilst there are others that can only find support on some one kind, the leaves of some particular species of plant, for example.

The habits of Caterpillars are extremely various. Some burrow into the substance of leaves, in which they excavate galleries; others envelop themselves in the membrane of the leaf itself. Many construct cases or sheaths, either fixed or portable, by agglutinating various substances together; and there are some which live in societies, living together under a tent of silk which they spin in common, and which serves to defend them from the inclemency of the weather. They usually throw off their skin four times before undergoing the transformation into the chrysalis state. For this they prepare by spinning a *cocoon*, in which they are enclosed during the greater part of that epoch. Some construct this entirely of silk; others attach together portions of leaves or particles of earth by silken threads. These threads are formed by a glutinous secretion from glands which seem analogous to the salivary glands of other animals; and this being forced out through a small opening at the end of the lip, hardens as it dries in the air. There are some caterpillars which form no cocoon, but which are contented with suspending themselves by the attachment of the hinder part of the body to some solid support, or by a silken thread coiled around them. The *chrysalis* or nymph has the whole body enclosed in a tough envelope, under which, however, the form of the parts of the future insect may be discerned. At the moment of the final transformation, it discharges from its intestine a red liquid, which softens one end of the cocoon, and allows the exit of the moth. Generally one end of it is weaker, or even fitted by the arrangement of the threads for the escape of the insect.

The *Butterfly*, when it throws off its last envelope and comes forth into the air, of which it is henceforth to be one of the gayest inhabitants, is not altogether perfect, although capable of very soon becoming so. The wings appear at first very slightly developed, and hang loosely by the sides; and it is not until the animal has injected their tubes with air, by taking several full inspirations, that they become expanded so as to serve for flight. From that period, the body is by them during by far the greatest proporti active state.

The order of *Lepidoptera* is usually divided sections, which are different alike in their cu and habits. These are—1. The Diurna, or which may be at once recognised by the ver tion of the wings during repose; 2. The laria, or *Twilight-Moths*, commonly known *Moths*, in which the wings are horizontal in re the antennæ thick or club-shaped; 3. The or true *Moths*, whose wings are also horizon clined in repose, but whose antennæ are mor tapering gradually from the base to the point

Section I. Diurna.—The first section co with the Linnæan genus *Papilio*, which is a ever, very much subdivided. The Butterflies tinguished from other Lepidoptera by the le their colouring, and by the beauty of the und as of the upper side of the wings. Their ca have generally sixteen feet, and their pupæ a always destitute of any silken envelope, and are by the tail. The antennæ of Butterflies are knobbed at their extremities, sometimes of thickness throughout, and sometimes taper from base to point. This section may be div three families, according to peculiarities in t morphosis.

Section II. Crepuscularia.—The section c cularia, or *Hawk-Moths*, corresponds with the genus *Sphinx*, which derived its name from th attitudes (resembling that of the sculptured antiquity) into which the larva sometimes thr Although the Lepidoptera arranged under thi on account of their similarity of structure, a twilight-fliers, it is not the case with all; for some which come abroad in open daylight, the juices of flowers with their long trunks, sun is brightly illumining their wings. The are observed to be more brilliantly coloured rest. In most of the Sphinges the body and w a dull brownish-grey aspect, like that of mo whose habits are similar. The wings are mo in appearance than those of the Butterflies, scales did not lie so closely upon each other. T of the Crepuscularia have always sixteen feet, pupæ are either enclosed in a cocoon or ha selves in the earth. The Hawk-Moths ma humming noise in their flight.

without having yet thrown off its larva skin.
eady to escape, it scales off the anterior end of
like a cap. Many larvæ, however, do throw

sections. In the first, NEMOCERA, the antennæ are composed of more than six joints; whilst in all the remainder, the antennæ are short, not having apparently more than three distinct joints. In the second, NOTACANTHA, the last division of the antennæ is really composed of two; the proboscis does not project much from the mouth, and is furnished with only two lancets. In the third, TANYSTOMA, the antennæ have really only three joints, the last being usually terminated by a *seta* or bustle. And in the fourth, the ATHERICERA, the antennæ are only two or three jointed, and the proboscis is withdrawn into the mouth.

Section I. NEMOCERA.—To the Nemocera belong the two families of CULICIDÆ and TIPULIDÆ; the former known as the *Gnat* tribe, the latter as the *Harry-long-legs*. The former are distinguished by their beautifully tufted antennæ. Gnats are well known to abound chiefly in damp situations; the reason being that their larvæ are inhabitants of the water. In this state they are very active, swimming with great agility, and often descending, but coming to the surface to breathe, which they do head downwards, the respiratory orifice being at the end of the tail. When the final transformation occurs, the skin of the pupa, which is being cast, serves as a kind of raft, which prevents the perfect insect from being immersed in water. The mosquitoes which infest many countries, especially in warm latitudes, differ but little from the common gnats. They sometimes appear in such swarms, especially in marshy districts, as to be kept off only by fire.

Section II. NOTACANTHA.—The second section of the Diptera contains three families, STRATIOMIDÆ, BERIDÆ, and CŒNOMYIDÆ, which do not attract much attention, although some of the insects contained in them are very abundant. They are mostly small, but gaily-coloured insects, and are most numerous in moist situations, in which the larvæ are generally produced. They mostly feed upon vegetable rather than animal juices.

Section III. TANYSTOMA.—The insects composing the third division have usually a more perfect mouth than those of the other sections; and they are also remarkable for the structure of the head of the larvæ, which possess two claw-like appendages, by which they

order, but it is even difficult to assign their pro-
ce in the class. As they possess less of general
t than of curiosity to the scientific naturalist,
need not here be treated of.

WINGLESS INSECTS.

des the foregoing orders, which constitute the
sects, three others must be included in the class,
unt of the correspondence in their general struc-
although they present only one or neither of the
aracters which have been stated to distinguish
presence of wings in the perfect state, and the
orphosis. These three orders are, the APHANIP-
R *Flea* tribe, which have the rudiments of wings,
dergo a metamorphosis; the PARASITA, or *Louse*
hich is entirely destitute of wings, and under-
metamorphosis, but agrees with the true insects
ng only six legs; and the THYSANURA, including
ring-tails, in which there are appendages to the
en, representing the legs of the posterior seg-
so that these may be regarded as approaching
riapoda.

Order XI.—Aphaniptera.

order contains only one family, the PULICIDÆ,
tribe, all of which are insects of minute size,
e the Diptera (to which they are perhaps most
allied), of suctorial habits. Their larvæ come
om the egg in the form of minute worms, pos-
considerable activity, and feeding upon animal
a provision of which seems to be formed for
y the parent. They afterwards enclose them-
in a small cocoon of silk, which is often covered
ust, and in this they undergo their change into
a state. In their perfect state, the rudiments
wings are visible, in the form of little scales,
d to the second and third segments of the body,
h there is no proper distinction of thorax and

entirely destitute of eyes.

Order XIII.—Thysanura.

e insects of this order there is a remarkable
y of structure, especially in regard to the mouth.
them possess as complex an oral apparatus as

the mandibulate insects, whilst in others there is scarcely a perceptible opening. The same is the case with regard to the eyes; these organs being fully developed in some, and almost rudimentary in others. The order contains two families. In the first, the LEPISMIDÆ, the abdomen is furnished on each side with a row of moveable appendages, like false legs, and is terminated by long jointed bristles, of which three are more remarkable. These little insects leap very well; some frequent stony places, whilst another is found in sugar, and is known as the *sugar louse*. In the PODURIDÆ, the appendages to the sides of the abdomen are wanting; but the extremity of it is prolonged into a forked tail, by which these insects can execute very surprising leaps; this, when in inaction, is applied against the belly. From this conformation they are popularly known under the name of *Spring-tails*.

Podura Villosa.

CLASS VII.—ARACHNIDA.

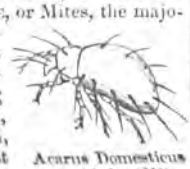
The class of Arachnida, including the *Spiders* and their allies, was for a long time confounded with that of Insects, and has been only recently separated. The characters which they present are perfectly distinct from those either of Insects on the one hand or of Crustacea on the other; nevertheless they present numerous relations with both those groups.

The Arachnida may be distinguished from Insects by the absence of any division between the head and thorax; and the compound mass thus formed is termed the cephalo-thorax. Again, Insects in their mature state are always provided with six legs and no more; the Arachnida have eight of these members. Moreover, the eyes are not compound, but more resemble those of higher animals. From Crustacea they are separated by the softness of their bodies (in which respect, however, they are approached by certain Macrourous Decapods termed Spider-Crabs), but still more completely by their exclusively atmospheric respiration. The organs by which this function is performed vary in different tribes. In the *Acari*, or Mites, and their allies, they resemble the tracheæ of insects, and are distributed through the body, whilst in the Spiders, Scorpions, &c., they consist of rounded cavities, or air-sacs, into which the air is admitted by spiracles situated on the abdomen, and which are lined by a membrane plaited into numerous folds, which resemble gills, and lie in apposition like the leaves of a book. On this character is founded the subdivision of the class into *pulmonary* and *tracheary* Arachnida.

The majority of the Arachnida feed upon insects, which they seize alive, or upon which they fix themselves, and from which they suck the juices. Others live as parasites upon the bodies of vertebrated animals. There are some, however, which are only found in flour, cheese, and upon various vegetables. These last, which mostly belong to the tracheary order, exhibit an affinity to Insects not only in their structure but in their metamorphosis; for they undergo great changes after they come out of the egg, an additional pair of legs being often developed; whilst in the others nothing else than a moult or casting of the skin occurs.

Order I.—Trachearia.

The Trachearia, being the most nearly allied to Insects, are naturally the first to be considered. This order contains several remarkable forms, of which the one best known is that of ACARIDÆ, or Mites, the majority of the species of which, however, are very minute, or almost microscopical. They are very extensively distributed; some being inhabitants under stones, leaves, bark of trees, in the ground, upon articles of food; whilst others subsist as parasites upon the skin and in the flesh of different animals, greatly weakening them by their excessive multiplication. There are some species which infest, especially the carrion beetles. Some of this order resemble spiders in form and habits.



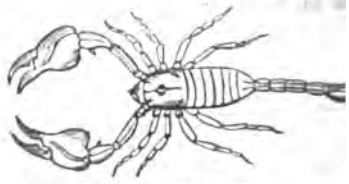
Acarus Domesticus magnified. (Mite.)

Besides the *Acari*, which form the principal part of this order, there is a curious group, which bears the name of *Pseudo-Scorpions*, owing to their possession of a pair of large claws terminating in forceps, like those of the true scorpions, are formed by the excessive development of the organs which in insects are termed palpi. There is also a very small family, which some naturalists have separated as a distinct order, the *Pycnogonides*; these are distinguished by the absence of all special respiratory organs, and their aquatic habits bear a strong resemblance to the Crustacea. They are found amongst marine plants and under stones on the beach. Their motions are remarkably slow; and they are said to live chiefly upon the animals of Bivalve Mollusca.

Order II.—Pulmonaria.

In this order, the respiration is performed by means of air-sacs contained on the under side of the body, and opening externally by stigmata; sometimes these structures are eight in number, four on each side, sometimes four, or even only two. This diminution appears to indicate a gradual elevation in the characters of the apparatus; leading us from the diffused condition in which it exists in Insects, to the more concentrated form it presents in higher animals. The Pulmonaria possess eight breathing-pores; and thus approach more to the Tracheary Arachnida than do the Spiders, which offer themselves next, therefore, to our consideration.

The family of PEDIPALPI is distinguished from the Araneidæ principally by the great development of the palpi, which form extended arms, terminating in a forceps or claw. The entire body is clothed with a tough skin. In the *Scorpions*, which constitute the principal part of this family, the abdomen is very much elongated, forming a sort of tail, which is terminated by a sting, and furnished with a venomous secretion. The



Scorpio Occitanus.

this sting, although very painful, does not prove ordinarily dangerous. A small species is found in this country; but it is between the tropics that the Scorpions attain their greatest development. They live chiefly on the ground, hiding themselves under stones, the loose bark of trees, dead bodies, among ruins, where such exist, and in other cool places generally, even the interior of houses. They run quickly, and curve the tail over the back, so that they can turn it as an arm of offence or defence.

Besides the Scorpions, there is included in this order the tribe of *Tarantula** Spiders, which are intermediate in several respects to the Scorpions and the true Spiders.

The other family of the pulmonary Arachnida consists only of the Spiders, of various kinds, and is designated ARANEIDÆ. In these, the palpi are not developed to any thing like the same degree as in the preceding tribe; they rather resemble feet; but the jaws are furnished with sharp and hooked fangs, and are perforated at their points, for the emission of a poisonous fluid, provided for the destruction of their prey. Several of them are provided with organs, situated at the hinder part of the body, for spinning a very delicate

* These are not the animals known in the south of Europe by the name of Tarentula, receiving their designation from the city of Tarentum; the latter are true Spiders.

it the use to which it is to be applied varies in pecies. In some it forms webs in which are the insects on which they feed; in others, it d to make a delicate silken tube, which lines tation; and in others, it is chiefly used for ation of a sort of cocoon with which the eggs nded. The instruments by which this thread d are little teat-like protuberances, termed , of which four usually exist at the posterior of the abdomen. Each of these, when highly , is found to be perforated at its extremity by ole orifices of extreme minuteness, through rced out a glutinous fluid, secreted by glands his fluid soon hardens by exposure to the air; each thread, delicate as it may seem, is com- veral hundreds, of extreme minuteness, coiled o that it possesses great strength in proportion neter.

iders are all extremely voracious in their ding only upon prey which they have them- ed. When they have got an insect between s, either by entrapping it in their web or by thy mode of pursuit, they plunge their poisoned into its body, and the bite is usually soon metimes, however, the insect has strength resist its enemy, and to prevent the infliction d wound; and, as a prolonged struggle might jurious to the spider, on account of the soft- body, it generally retires from the contest if lily successful. Where its prey has been in its web, however, the spider still further : by a silken thread, and then retires until the lost its strength by ineffectual struggles, when patches its victim.

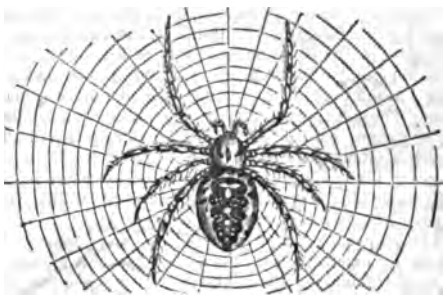
Mygale Fodiens.

ho is remarkable for the curious habitation onstructs for its young. It spins a kind of coon or tent, which it attaches to the under es or to crevices in rocks by seven or eight ving festoons between these, the edges of free. At first this consists of only two folds, are gradually added; and beneath them all peculiarly soft texture is constructed for the of the eggs. The young remain in this ter after they are hatched, and are supplied by with food. The *Argyroneta* forms a winter itself beneath the water. It spins an oval mber, open at the bottom like a diving-bell, attaches by cords to water-plants. It then wn successive bubbles of air beneath its body, g down their stems; and these bubbles it to its bell until it has filled it. It then takes de in this cell, where it remains for the winter, ng the mouth of the bell. The *Epeiræ* are most remarkable for the strength of their e of the exotic species, which are remarkable for the variety of their forms, colours, and habits, spinning nets which are sufficiently strong to catch small



Epeira Diadema.

birds, and even to annoy man when he happens to come in the way of many together.

CLASS VIII.—CRUSTACEA.

The animals composing this group may be regarded as representing in the sea the insects and spiders of the land. Indeed, they were associated with those classes by Linnæus, in his class of Insects. But they are separated from both by very important characters. Their chief distinction is in the breathing-apparatus, which is adapted to aquatic and not to aërial respiration. Instead of the system of branching tubes which we find in Insects, or the lung-like cavities which are a more concentrated form of the same structure in the Arachnida, the Crustacea are furnished with fringes of gills like those of the Mollusca or Fishes, into which the blood is sent, as it were, out of the body, to meet the small quantity of air contained in the surrounding water. In the highest order of this class, the gills do not hang loosely from the body, but are enclosed in a cavity, having two orifices, through one of which a constant stream of water is introduced, which is ejected through the other by a curious mechanical contrivance. And in a few species of this order, there is a special provision for keeping the gills moist when the animal leaves the water, out of which it can live for a considerable period. The best-known of these are the Land-Crabs of the West Indian Islands.

It is not only by their aquatic respiration, however, that the Crustacea are distinguished, but also by the calcareous nature of their integument. The shell, as it is commonly termed, is a secretion from the surface of the true skin, just as are the shells of Mollusca from their mantle. There is this important difference, however, between the two, that, whilst the latter is merely adapted to enclose loosely and to protect the general mass of the body, so that the locomotive appendages, when put in action, must be made to project beyond it, these being themselves unsupported by any hard skeleton, the former accurately fits not only the trunk but the extremities also, and, as in the other Articulata, is composed of a number of rings, more or less regular in form, and accurately jointed together by an intervening membrane.

As no addition to the edges of these rings would increase their diameter, some other means must be provided for enabling the size of the shell to keep pace with the increasing bulk of the body. This is effected by the periodical *exuviation*, or throwing off of the old shell, and the formation of a new one. This change is preceded by evident illness on the part of the animal, which retires to its hiding-place at the time. The part of the shell enclosing the trunk splits usually at its under part, in such a manner as to allow the body to escape; but the shell of the legs and claws remains entire, though the fleshy parts are entirely withdrawn from their interior. This is the more remarkable, as the bulk of the claw is much greater than the diameter of the joint through which it is thus made to pass; and

below that point, the animal itself effects the removal of the upper portion, either simply casting it off by violent muscular contraction, or striking it against some hard body. The same is the case when the claw has been accidentally lost in some other way; and, accordingly, it is by no means uncommon to witness a great disproportion in the size of the two members, one being much smaller than natural, from its having been only recently produced.

The number of legs possessed by the Crustacea is greater than that of perfect insects, being never less than four pairs, besides the pair of claws which may be considered as metamorphosed legs. It is in the crab, lobster, crayfish, &c., that we find this small number; and these belong to the highest order, the Decapoda, or ten-footed Crustacea. In front of these are some curious organs termed feet-jaws, being intermediate in structure between these two kinds of appendages; in some of the lower Crustacea these become true legs. And from the posterior part of the body there hang down certain appendages, which are also true legs in the lower orders. In fact, the lowest Crustacea approach very closely to the Myriapoda in their general form and structure, differing chiefly in their aquatic mode of life; the segments of the body are nearly equal, and are each furnished with a pair of legs. On the other hand, among the Decapods we find an approximation to the form both of insects and spiders—the lobster representing the one, and the crab the other. In the lobster we have a regular division into *head, thorax*, and *abdomen*, as in insects; and it is to the thorax alone that the locomotive appendages are attached, as in the perfect state of the insect. There is no rudiment, however, of wings. As in the insect, we find that, where the force is concentrated in one part of the body, and the general movement is effected chiefly by the members, the segments of that part are consolidated; and, accordingly, the thorax of the lobster seems, until carefully examined, as if composed of a single piece. The segments of the abdomen, however, are moveable on each other; and their motions assist in progression, the flattened tail serving as a fin by which the water is

a sucker. These two groups are precisely to those of Mandibulata and Haustellata amo The Edentata are divided into three orders, to the form of the extremities:

Araneiformes, in which the extremities ar long, and adapted for walking.

Syphonostomata, in which the extremitie adapted for walking, are partly formed into partly adapted for prehension.

Lernæiformes, in which the extremities little developed, and the body presents great form. Most of these are parasitic upon othe especially fishes, to which they cling by mean in which their rudimentary extremities term

The Maxillosa, containing by far the larg tion, as well as the most highly organised fo class, are again distributed into four section Dophthalmia, in which the eyes are mounted stalks, and are moveable. These have alm branchiæ, properly so called; their feet are bulatory, partly prehensile; and the thorax with a *carapace* or shield (like the upper sh turtles), which is formed by the great devel one of the rings, overlapping the rest. 2. Em mia, in which the eyes are *sessile*, or not mou pedicle. The branchiæ are not separate orga united with the extremities; these are almo seven on each side, and adapted for walking. no carapace. 3. Branchiopoda, in which the gills, but the anterior pairs of legs are flatt plates, which are subservient to respiration tomostraca, in which there are no branchiæ, parent organs to supply their place. The sessile, and commonly united into a single mas groups are again subdivided into nine order lows:—

1. The Podophthalmia consist of the Dec which there are five pairs of thoracic extrem which have the gills enclosed in a special re cavity; and the Stomapoda, which have six pairs of thoracic extremities and external bra

2. The Edriophthalmia contain three or

Branchipus Stagnalis.

teristic examples, is found, often in great ers, in small puddles, and most abundantly heavy rain. The eggs are capable of being up without injury, and are hatched soon afte g moistened.

Order VIII.—Copepoda.

The animals of this and the next order are commonly termed *monoculous*, from the two eyes being united into one mass. In their general habits they agree with the former. The *Cyclops* is an interesting species, very common in the ponds and ditches of this country. The female has an oval sac on each side of the tail, in which the eggs are carried. She is able to produce ten broods in the course of three months, and as these are speedily able to reproduce themselves, it has been calculated that in a year, 4,442,189,120 young may be the progeny of one individual. The majority of the animals of this order swim with the back downwards, darting about with great agility, and moving backwards or forwards with equal ease. In the absence of animal matter, on which they usually feed, they attack vegetable substances.

Cyclops Vulgaris, magnified.

Order IX.—Ostrapoda.

In habit and general character, the animals of this order, of which the common *Cypris* of our ponds is an example, closely resemble those of the last, but their bodies are enveloped in a sort of bivalve shell. They swim, like the *Daphniæ*, by means of the prolonged antennæ, which spread at their extremities into tufts of filaments.

The animals of the division Edentata are nearly all parasitic. In their general organisation they are the most imperfect of all Crustacea, some of them approaching the higher Entozoa, whilst others have a resemblance to the lowest Arachnida. The various species of these orders, which need not be more minutely particularised, infest, more or less, almost all marine animals.

There now only remains the remarkable order *Xyphosura*, separated from all the rest by the absence of any special organs for conveying food into the mouth. It receives its name from the sword-like prolongation of the carapace, which is used as a weapon by the natives of the regions in which the animals exist. The *Limuli*, or King-Crabs as they are commonly termed, are peculiar to the East Indies (abounding in the neighbourhood of the Molluccas) and the coast of America. They sometimes attain the length of two feet. Their legs are very short, not extending beyond the margin of the shell. The anterior ones seem to assist in conveying food to the mouth; and the posterior are modified for respiration.

y organs are here developed internally, the ani-
ng formed to crawl upon the ground instead of
ng through the water. And in the last, SUCTO-
body is destitute even of these bristles, but is
d with a sucker at each end of the body. The
er groups were regarded by Cuvier as forming
er.

Order I.—Dorsibranchiata.

e foregoing orders, the Dorsibranchiata appear,
hole, to possess the most complex structure, as
the most varied faculties, and they also exhibit
t characteristic forms of the class. The head
t always distinct from the body, and furnished
ghly-developed organs of sensation, as well as
nplex instruments of mastication. These marine
do not attain any considerable dimension upon
coasts, rarely exceeding a few inches in length;
ropical climates some species are found of some-
ly gigantic proportions, having their bodies
ed of 400 or 500 segments, and occasionally
ing four feet from one end to the other. Their
form will be seen in the accompanying figure,
epresents the *Syllis Monilaris*; and the enlarged
one of the lateral appendages will show the para-
ch it consists. In the centre there is a tuft of
e bristles, which may be regarded as the chief

Syllis Monilaris, with an enlarged representation of one of its appendages.

organ of respiration, the blood being sent into them to be exposed to the air contained in the water; above and below there are separate bristles, much more elongated, of which the lower one has a jointed character; these are instruments of locomotion, and may be regarded as rudimentary legs. The arrangement of these parts differs much, however, in the various tribes of this order.

Among the more interesting forms of this order may be mentioned the family Nereidæ, or Sea-Centipedes, of which many species inhabit our own coasts, but much larger ones are found in tropical seas. They have no venomous power, but are extremely voracious; and are often furnished with a complex apparatus for seizing their prey and reducing it to fragments.

The *Aphrodita* is an animal well known on our coasts under the name of *Sea-Mouse*; numbers are often cast up by a gale of wind. The body is flattened, and shorter and broader than that of other Annelida. The back is covered by two longitudinal ranges of broad membranous scales, under which the gills lie concealed. The most common species of Sea-Mouse are about six or eight inches long, and two or three broad. A great part of the body is covered by bristles of brilliant lustre, and of colours which vary with the light; so that the animal is scarcely surpassed in beauty of colouring by any other. The *Arenicola piscatorum*, known to fishermen by the name of *Lob-worm*, is another species common on our coasts, and is eagerly sought as a bait. It burrows, like the earth-worm, in the sand; and the place of its excavations may be known by the little heaps which it casts up. The branchial tufts are confined to the centre of the body, where they form on each side a series of bunches, which are remarkable, during the life of the creature, for their beautiful red colour, derived from the crimson blood which circulates copiously through them.

Order II.—Tubicolæ.

Comparatively little is known of the structure of the animals of the order Tubicolæ, which never attain to such great dimensions, and do not offer to the naturalist the same facilities for examination. The structure of the casings which they form, however, has been fully investigated. One of the commonest of these is the shelly tube exuded by the *Serpula*. This is formed of calcareous matter resembling that of the shells of Mollusca, and apparently secreted from the surface of the body in a similar manner. These tubes, which are often very greatly contorted in form, are generally found encrusting the surface of stones or other bodies which have been immersed for any length of time at the bottom of the sea; they are closed at one end, which tapers to a point, and the wide end is open.

Serpula Contortuplicata, taken out of its tube.

The animal forming this shell has its branchial filaments all assembled round the head, where they form a pair of most elegant fan-like appendages, which usually possess very brilliant colours. At the base of each tuft is a fleshy filament; and one of these, on the right or left side indifferently, is always prolonged and dilated at its extremity into a flat disk, which fits to the mouth of the shell, and serves to close it when the a withdrawn into the tube.

The *Sabella* is an animal very much re the Serpula; but it constructs its tube by nating particles of clay or fine sand. The forms a similar tube, by cementing togethe shells and fragments of larger ones, toget particles of sand, gravel, &c.; and some sp in aggregate groups, so that the clustering of their tubes forms solid masses, which a increasing to a considerable size. In none cases is the shell or tube to be regarde of the animal; it is merely its habitation. nelide forms no muscular attachment to it, an can be easily drawn forth from its interior.

Order III.—Terricola.

The order Terricola includes very few which the *Lumbricus*, or common *Earth-wo* chief. They live in general beneath the surf ground, either perforating the dry soil, o themselves in mud, where many of them lea aquatic life. When the Earth-worm is insinuates its pointed head between the pa earth, amongst which it penetrates like a w in this position, the anterior part of the body spines or bristles curved backwards, which from slipping. The hinder parts are then d wards by a longitudinal contraction of the wh —a movement which the spines do not opp swells out the anterior segments, and force the passage into which the head had bee thrust. The spines upon the hinder rings th firm hold upon the side of the hole, thus for prevent any backward movement; the hea forced forward; and, by a repetition of the p animal easily makes its way through substa it would at first have seemed impossible for i trate.

The burrowing of Earth-worms is a proce ingly useful to the gardener and the agricultu these animals are far more beneficial to m way than injurious by devouring the vegeta the soil. They give a kind of under-tillage t performing the same below ground that the s above for the garden, and the plough for ar and loosening the earth so as to render it p to air and water. It has lately been shown will even add to the depth of the soil, and cre where none existed before. This they do p by the exercise of their digestive process. a large quantity of the soil through which th into their intestinal canal; from this they e greater part of the decaying vegetable mat contain, and reject the rest in a finely divi forming what are known as worm-casts. By mulation of these, a field which was manu marl has been covered in the course of sig with a bed of earth averaging thirteen inches ness.

It is commonly supposed that the Earth-w be multiplied by the division of its body into t of which each will continue to live. This appear to be the case. If it be divided across th when in motion, each will continue to move fo but only the piece which bears the head will alive after a few hours. This forms a new soon shows little sign of the injury. But if th be made near the head, the body will remain a will renew the head; and the head with its few segments will die. The *Naides*, however, hav greater amount of reproductive power; for t be cut into many pieces, of which each will b perfect animal; and it is stated that a separati place spontaneously, but to a much greater ex

Order IV.—Suctoria.

The order Suctoria contains the common Le its allies, which are all animals of aquatic ha

ng in its blood-seeking propensities. Most however, live at the expense of some other

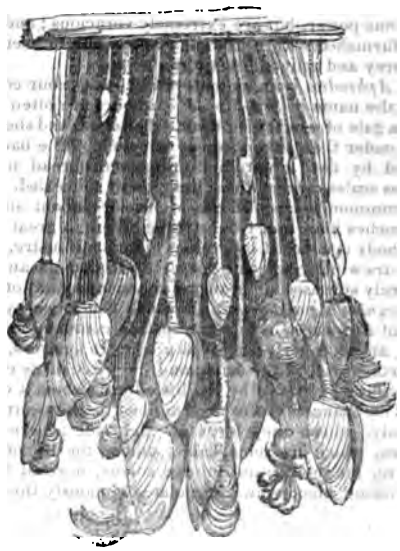
Its body is prolonged, a tendency to division into segments; and these there arises a pair of appendages on ich possess something of a jointed struc- cirri, as they are termed, are long taper- nged with cilia, or little hair-like filaments; e gills at their base. Further, the mouth with lateral jaws, which no Mollusca pos- e nervous system consists of a double cord, f ganglia in each segment of the body, pre- he other Articulata. The most interesting er, that the Cirrhopoda belong to this divi- ed from the history of their development. eration from the egg, they present a form analogous to that of the lower Crustacea of the adult animal, which they only ac- series of metamorphoses. They are fur- ntennæ and eyes, and move freely through ut when they become fixed they lose also of sense. The shell is not formed of simple hat of the Mollusca, but is traversed by a complex series of canals, through which nourishment is conveyed to it.

The Cirrhopoda are divided into two principal groups —the *pedunculated* and the *sessile*. The latter, of which the common *Balanus* or *Acorn-shell* is an example, have the base of the shell fixed immediately to rocks. In the former, such as the well-known *Barnacle*, the shell is attached by a peduncle or footstalk, which consists of a tube of leathery consistence, and is often of considerable length. In both groups, the animals, not being able to go in search of food, obtain it through the currents produced by the action of their cilia.

The shell of the common *Barnacle* consists of five pieces, of which two are large valves, somewhat resembling those of a mussel; two smaller pieces are jointed to these near the point; and one unites the valves along the back edge. These cover the whole of the mantle. Barnacles are abundant in all seas, and fix themselves, in preference, to wood; so that a piece of timber which has been for a short time floating in the ocean is almost sure to be partly covered with them; and ships' bottoms, if not protected by copper, are rendered so foul as greatly to impede their sailing.



Group of Anatifa, attached to a ship's bottom.

The *Balanus*, or Acorn-shell, has more of a globular shape, with a narrow mouth, and is composed of a certain number (varying in the different species) of plates, of a triangular form, so disposed, that an addition to the edges of each shall preserve the general proportions of the shell, whilst increasing its cavity in all its dimensions in accordance with the growth of the animal. In this arrangement we recognise the same plan as that adopted in the shell of the echinus. The animal closely resembles the barnacle. The mouth of the shell is guarded by an *operculum*, consisting of two or more valves, which close it more or less completely. The rocks, piers, &c., on many parts of the coast, are covered with these animals; and small species of them also attach themselves to shells of various kinds.

CLASS XII.—ROTIFERA.

The class Rotifera is one composed entirely of animalcules which can only be distinctly seen with the microscope; and it takes its name from the wheel-like organs with which most of them are provided, whence they are commonly known as Wheel-Animalcules. It is only within a very recent period that the complex structure of these beings has been understood, and that they have been separated from the animalcules of simpler organisation. It is on account of the prolonged

form of their bodies, the position of the mouth and eyes at one extremity, the occasional marking of transverse lines indicating a division into segments, and most of all by the character of the nervous system, when that can be detected, that the Rotifera are ranked in the articulated sub-kingdom. Unquestionably, they bear more general analogy to that than to any other; but they must not be considered as characteristic specimens of it.

The structure of the common wheel-animalcule, *Rotifer vulgaris*—which may be found in many collections of stagnant water, especially such as have been long and freely exposed to the atmosphere—will afford a good illustration of that of the class. The body exhibits a prolonged form when fully extended; but, as the integument is very elastic, it may be drawn up into a circle or made to assume a great variety of shapes. At one end it is furnished with a pair of projections, which are surmounted by circular fringes of cilia. It is by the vibration of these cilia that the currents are produced in the water around, which give an appearance as of the continual revolution of wheels. Between the wheels a sort of head extends forwards, on which a couple of red spots may be observed, which are believed to be eyes. The mouth is situated at the base of this central projection. At the opposite end the body is prolonged into a sort of tail, furnished with three prongs; and by this the animal fixes itself when working its wheels for obtaining food.

The delicate membrane which covers the body has two series of muscular fibres disposed within it; one set running longitudinally from end to end; the other transversely, so as to form rings around the body. By the contraction of the former the body is shortened; by that of the latter its diameter is decreased, and it is consequently lengthened. This is the same kind of apparatus as that by which the form of the leech and worm tribe is altered. The transparency of the integument allows the contained organs to be distinctly seen; and these are perceived to have regular membranous walls of their own, and to be altogether distinct from the general substance of the body. The most curious of these is the gizzard, or set of jaws (as it may perhaps be termed) in which the food is ground down before it is transmitted to the true stomach. This is placed in the fore part of the body, and principally consists of a hard framework in two pieces, each of which bears two teeth. The two frames are moved by powerful muscles, and worked in such a manner that the teeth are made to interlock and to separate alternately, so as to tear all the food which is transmitted into the stomach. From the stomach there passes backwards a long straight intestine, which terminates near the posterior part of the body.

These animalcules feed chiefly upon others of smaller size and simpler character. The currents set in motion by the cilia are very powerful, and draw in whatever small bodies are within their scope; and the animal seems to select from these what is adapted to afford it nutrition. Sometimes it folds in its wheels, and moves along a solid surface by the suckers with which its head and tail are furnished, in the same manner as a leech; and sometimes it remains altogether inert for a considerable period. One of the most remarkable points in its history is its power of being revived by the application of moisture, after having been entirely dried up. This experiment, however, does not always succeed.

The Wheel-Animalcules are propagated by eggs, the development of which within the body of the parent may be very distinctly seen, on account of the transparency of the latter. These eggs are large and not very numerous, seldom more than four; but they rapidly arrive at maturity, and are soon capable of producing others. It has been calculated that, from a single individual, more than a million may be produced in ten days. In some of this class, the eggs are borne for some time on the outside of the body, attached to its posterior part, as in the *Cyclops* and other minute Crustacea, to which the general structure of the higher species of Rotifera shows them to be nearly allied. Oth connect this class with the higher Polypifera.

CLASS XIII.—ENTOZOA.

This class derives its name from the peculi tion in which the animals composing it exist, them being inhabitants, during their whole li bodies of other animals, generally those of hig nisation, from the juices of which they der nourishment. Many of them possess a distin like form, the body being much prolonged, an ing a division into segments, and the mouth b ated at one extremity. These, therefore, belong to the Articulated series. There a which, in the absence of all distinct organs, s the circularity of their form, seem to approxi to the Radiata. Some species, formerly lon class, are now known to be low kinds of Cru

A division of the Entozoa into two sections proposed, founded upon the general peculiarit structure, which it may be useful here to r the first and highest of these, there is a dist tinal tube, with an orifice at each end; and nervous and muscular system, more or less may be detected. This division evidently ap to the Annelida. It includes, among many ot the *Filaria*, or Guinea-Worm, which burr flesh of man and other animals in warm c undisturbed, it will often continue its opera considerable time without much uneasiness; turbed, it sometimes occasions the most e pain. When it shows itself externally, it is very slowly, for fear of breaking it, in whic remainder would retreat, and continue t grows to the length of several yards. T *lumbricoides*, or Round Worm of the inte belongs to this group. It infests not only many of the lower animals, and often occas disease and even death. It derives its spec cific name from its resemblance to the ea The short active Thread-worms, sometime the lower part of the intestine, are another the same genus.

In the lower division of the class, there is alimentary canal; the cavities for the recepti as well as those for other purposes, being, channelled out of the soft, almost homogeneo of the body. Some of these still preserve the form. Such are the so-called eels in vinegar curious little parasites which have been re covered to infest the muscles of man. To also belongs the *Tænia Solium*, or Tape-Worm we find a remarkable repetition of organs. is distinctly divided into joints or segmen sometimes amount to several hundred, the mal occasionally attaining the length of ten fe segments are all connected by the nutritive ca runs from one end to the other; but the re apparatus is repeated in each division. T small, and possesses four mouths, surrou double circle of small hooks. Its existence to the life of the body, the latter dying if it off; but if some of the joints remain attac head, it continues to grow and form new on repetition of parts, we see a tendency towar of the Polypifera.

One of the most simple of all the Entozoa mon *Hydatid*, or Acephalocyst (headless) seems to consist of nothing but a globular t bag filled with a limpid colourless fluid, no motion or indication of sensation, whe any kind are applied to it; and it is often distinguish it from the tissues in which it l power of reproduction, however, by the *gemmæ*, or buds between its layers, shows titled to the rank of an independent being Hydatids are thrown off internally or exter ing to the species.

mongst the animals associated with this group, gh not conforming with it in their residence, is the *aria*, a very interesting genus, of which some ies inhabit fresh water and others are marine. body is flat, and three or four times as long as d. Within its soft tissue are channelled out not a complex digestive cavity, but also a system of ls which absorb fluid from its walls and convey it ugh the system, and a reproductive apparatus. stomach opens, not by a mouth at one end, but by rt of sucker projecting from the middle of the body; through this the Planaria imbibes the juices of va- aquatic animals which it attacks, mastering even re little worms by twisting its body round them. most curious part of their economy consists in their er of reproducing parts that have been lost, and of iring injuries, which seems almost as great as that he Hydra among Polypes. They may be divided three parts, of which the former shall contain the minute spots which are believed to be eyes, the dle one the sucker, and the posterior one the repro- ive apparatus; and in a short time, each part will elop itself into a new individual, perfect in all its s. It may be partially split longitudinally from er extremity, so that two heads or two tails will be ed, uniting at the middle point, but each being plete in itself.

SUB-KINGDOM—MOLLUSCA.

he range of animal forms comprehended in this sion of the Animal Kingdom is so great, that it would lficult to include them by any definition applicable hem all. The highest class approaches Fishes in ny points of its organisation; whilst in the lowest not only lose sight of some of the characteristic aliarities of the group, but we find a near approxi- tion to the higher Polypifera. In all the Mollusca, body itself is of soft consistence, as its name imports, l is enclosed in a soft elastic skin, lined with mus- r fibres, which is termed the *mantle*. This skin, in ny instances, is not applied closely to the body, but as a membranous bag, having apertures (which are metimes prolonged into tubes) for the entrance and ss of water; and through these the respiratory ans, which are situated within the cavity, are regu- ly supplied with the pure fluid necessary for aërating ir blood; and the mouth, when it is not capable of ng projected beyond this cavity, is supplied with d by the same stream.

The Mollusca possess in general a very complicated strative and circulating apparatus; but the organs of tation and voluntary motion are comparatively un- eloped. The great bulk of their bodies is made up he stomach and intestines, the liver and other glands nected with the alimentary canal, the respiratory aratus, and the ovary for the production of germs ich is usually very large); and the muscular sys- which in the Articulata forms so large a propor- of the whole structure, is here frequently reduced few scattered fibres, and in but few instances at- any complexity and power. A considerable num- of Mollusca are formed for an existence as com- ely stationary as that of the Zoophytes, and are endent for their nourishment on the supplies of l casually brought within their reach by the waves currents of the ocean. A few, however, have ers of locomotion which enable them to search vely for it themselves; but the greater number der sluggishly, like the snail, from place to place, ouring with voracity such supplies as they meet h, and being capable of fasting for long intervals en none come in their way.

It is from the surface of the mantle that the calcareous tter is exuded which forms the shell, in those species ich possess such a protection; its particles are held gether by a sort of glue, which exists in much larger proportion in some species than in others. In very hard and brittle shells, if the calcareous matter be removed by the action of an acid, the animal matter that remains appears in the form of separate flakes. But in many other shells thus treated, the animal portion retains its form after the removal of the lime; and there are a few in which the (so-called) shell consists only of a substance like horn, without any intermixture of calcareous particles. Such a substance appears to be formed by the young animal before the true shell is secreted; and it is also the first that appears when the animal is repairing the effects of an injury to the old one. It is this that constitutes what is commonly termed the *epidermis* of shells—a covering possessed in their natural state by all that are not enveloped in a fold of the mantle, but which is commonly removed when the shell is preserved, as it impairs the beauty of the exterior. The shell is most solid and massive in those species which lead an inactive life; and is usually light and thin, or altogether deficient, in those whose powers of locomotion are greater. Its thickness often varies greatly amongst different individuals of the same species, according to the roughness or tranquillity of the waters they inhabit.

As the shells of Mollusca are the parts of their structure by which they were best known, it was natural that the first attempts at classification should be founded on their peculiarities. Accordingly, Linnæus arranged them into *Univalves*, *Bivalves*, and *Multivalves*, according to the number of pieces of which the shell is composed; and this classification, from its simplicity and the apparent facility of its application, has been very generally adopted. But, as will hereafter be seen, it is only within certain narrow limits that the character of the animal can be known by the structure of its shell; and, by the Linnæan classification, animals are brought together which are widely separated, and others are placed in distinct classes which are closely allied. Again, such a classification is totally inapplicable to the very numerous shell-less Mollusca, some of which approach so closely to those bearing shells (as, for example, the *Slug* to the *Snail*), that scarcely any essential difference exists. It is obvious, then, that although the characters derived from the shell may often be valuable in enabling us to recognise the remains of particular animals, classification must not be founded on them, but on the general conformation of the animals by which they are produced.

Following this principle, the Mollusca may be divided, first, into those having *a head*—that is, a prominent part of the body on which the mouth is situated, with organs of sense in its neighbourhood—and those which are *acephalous*, or headless. Among the former we perceive three very distinct types of structure.

The Cephalopoda, or *Cuttle-Fish* tribe, have feet or tentacula arranged in a circular manner around the head. In this group we find the nearest approximation to the Vertebrata.

The Pteropoda constitute a small but interesting class, characterised by the possession of a pair of wing-like expansions of the mantle, and by the great symmetry of their bodies. These expansions serve as fins, by which they swim through the water with great velocity.

The Gasteropoda are the most extensive group of the whole. The two former are confined entirely to the sea; amongst these we find species adapted to live in fresh water, and even on land. They have but one muscular expansion or foot, and this proceeds from the under surface of the body, as may be well seen in the Snail.

In each of these orders we observe a considerable variation in regard to the relative size and even the existence of a shell; for whilst there are some species in all of them which are entirely destitute of this protection (such being called naked Molluscs), there are others which possess it in a slight degree, having it generally concealed in a fold of the mantle, whilst in others it completely envelops the body, when they

CLASS XIV.—CEPHALOPODA.

The class of Cephalopoda, which is so named from the arrangement of the feet or locomotive organs around the head, must be regarded as the highest among the Mollusca in respect to the complexity of its organisation, and it is the one which approaches most nearly to Vertebrated animals. In the general form of their bodies, and in their adaptation to rapid motion through the water, many species bear a considerable resemblance to Fishes, and are, indeed, commonly reputed as such. The name of the class expresses the character which distinguishes it from all others. On the head, which is furnished with eyes resembling those of higher animals, and also with organs of hearing, and perhaps also of smell, are disposed in a circular manner the curious appendages, which have received the names of *feet* or *arms*, and to which either term may be justly given, as they are organs of prehension as well as of locomotion. These are usually eight or ten in number; but in the true *Nautilus* they are much more numerous, amounting to nearly a hundred.

The mouth, which is situated in the centre of the circle of arms, is provided with a pair of firm horny mandibles or jaws, of which one is sharply pointed, and overlaps the other when closed, so that the whole very much resembles the bill of a parrot. This beak encloses a large fleshy tongue, roughened with horny prickles; and the œsophagus leads to a muscular stomach, which much resembles the gizzard of birds. All the Cephalopoda are aquatic, and consequently breathe by gills. These are disposed symmetrically on the two sides, and are covered in by the mantle. This envelope includes the whole body, but there is an opening in it which gives passage to the head. Through this opening the water enters to the gills, and it is expelled through a tubular prolongation of the mantle termed the *funnel*, which also serves as the excretory canal for other fluids.

Most of the Cephalopoda possess something analogous to the shells of other Mollusca, although it often exists in a form and position which might almost prevent its

[illegible] Class.—The [illegible] armour of the [illegible] and its powerful claws, are no protection t these soft-limbed cuttle-fish, which wind round their bodies, and, fixing every part their suckers, tear apart the divisions of means of their hard parrot-like bills. S these suckers adhere, that, while the mu remain contracted, it is easier to tear away t of the limb than to release it from its attac

The Cephalopoda which are unprotecte ternal shell are furnished with a curiou escaping from their enemies. This is the a dark fluid, which, when emitted by the a the water around to such a degree that it c the cloud it has made. The fluid is usual in a bag communicating with the funnel, th it is ejected under the influence of alarm. T as it is termed, is collected from the specie the Indian seas; the ink forms a valua known to the artist as *sepia*, the name of which furnishes it.

The class of Cephalopoda may be subdivi orders. In the higher division, which app nearest to vertebrate animals, the *branch* are two in number, and the order is term CHIATA; whilst in the one most closely Gasteropod Molluscs, the branchiæ are n ber, and the order is therefore termed CHIATA.

Order I.—Dibranchiata.

The Dibranchiate order includes all the forms of the class. It is divided into tw one of which there are but eight arms, t other there are ten, of which, however, two from the rest. The first of these, termed may be considered as the highest in point organisation; the second, termed Decapo many points of approach to the Tetrabranc both in the increased number of arms, and sence of an inner circle of short tentacula, several internal characters. The *Sepia*, Cuttle-Fish, is a characteristic example of t

Order II.—Tetrabranchiata.

... om the remains preserved in a fossil state, the ... branchiata appear to have formerly abounded in ... seas; but the only living representative of them is ... *Pearly Nautilus* (N. Pompilius). In the animal ... h forms and inhabits the well-known chambered ... found on most tropical shores, we observe many ... rences from the usual type of organisation in the ... alopods. The arms are very numerous, amounting to nearly a hundred; they are unprovided with suckers; and they are short and slender, resembling closely the tentacula of many Gasteropods.

The head of the *Nautilus* supports a large fleshy disc, upon which it is believed that the animal crawls upon the bottom or sides of the ocean, as a snail upon its foot. The animal frequents deep waters; and, though it is occasionally found at the surface, it sinks upon the least alarm, so that it has been very rarely captured, although the empty shell is so common. This power of rising and falling in the water appears in some degree connected with the structure of the shell, and with the mode in which its chambers communicate with the body by a membranous tube which passes through all the partitions, and is called the *siphuncle*. But of the mode in which this operates no very satisfactory account has yet been given.*

A large number of fossil shells, analogous to that of the Nautilus, and hence called *nautilites*, are found in various strata, from the oldest limestones and sandstones of the Silurian system, to those covering the chalk.

CLASS XV.—PTEROPODA.

The Pteropoda are a small but remarkable class of Mollusca, distinguished by the adaptation of their structure for active locomotion in water only. Their general organisation is higher than that of the Gasteropods; and they are particularly distinguished by the possession of a pair of fin-like organs, which are attached to the anterior part of the body, and are evidently adapted for propelling it rapidly through the water. The body is uniformly symmetrical; that is, its two sides precisely correspond—a condition obviously favourable for rapid movement. It is from the wing-like character of these lateral appendages that the name of the class is derived.

The dimensions of the animals composing this class are uniformly small; but the number of individuals which associate together in shoals is often enormous, so that the sea appears literally alive with them. Some of them are possessed of a shell, whilst others are unprovided with such a protection. Wherever it exists it is very light and delicate; and it seldom covers more than the posterior part of the body. In one beautiful little Mollusc, the *Cymbulia*, it is of a slipper form, the wings or fins issuing from the large opening. The head is usually prominent, possessing eyes and sensitive tentacula; and the interior organisation is of very complex nature.

One of the best-known genera of this group is the *Clio*, which abounds both in the arctic and antarctic seas, and is a very important article of food to the whale. The aspect of this animal will convey a good general idea of that of the whole class. The Clio is itself eminently carnivorous, and in its whole organisation is fitted to seize and prey upon the yet more minute inhabitants of the deep.

The *Clio Borealis* is well known to the whale-fishers and others as *whale's food*; this species swarms in the

Clio Borealis.

arctic seas, and when the weather is calm, these little animals may be seen floating in myriads upon the sur-

* See Dr Buckland's Bridgewater Treatise for an attempt at explanation. This is deficient in its application to all those cases in which the siphuncle is a shelly not a membranous tube, as in the *Spirula*, *Ammonite*, &c.

face. According to Cuvier, the sea is sometimes so glutted with them, that the whales cannot open their mouths without engulfing thousands of these small molluscs. An analogous species, the *C. Australis*, appears equally abundant in the polar regions of the southern hemisphere.

CLASS XVI.—GASTEROPODA.

It is in the animals of this class that we find the characters of the Mollusca most prominently displayed, namely, the high development of the nutritive apparatus, with very feeble powers of locomotion. In all the more perfect forms, which are usually carnivorous, a distinct and prominent head exists, furnished not only with *tentacula*, or feelers, but also with eyes, and with what appear to be rudiments of organs of smell and hearing. In this part, we usually perceive that *symmetry* or correspondence between the two halves, which has been spoken of as characterising the *animal* organs in general; whilst in the posterior part of the body, which is made up of the organs of vegetative life, this symmetry is seldom to be discerned. They have the power of crawling from one place to another, by means of the expanded muscular disc or foot with which they are furnished; and as this foot proceeds from the belly or under surface of the animal, the class receives the name given to it. The mode in which it is used may be well seen by placing a snail or slug on a piece of glass, and looking at it from the under side. Many of those which inhabit the water can swim with considerable rapidity; but this power is chiefly possessed by those species which have no shell, or but a very slight one, and can bend their bodies in any direction.

The general character of the shelly structure, where it exists, is the same as in the Conchifera. It is in general composed of one piece, and called a *univalve*; in some instances, however, it is a *multivalve*; and in many species there is a small *operculum* or lid to the mouth of the shell, which may in some degree be regarded in the light of a second valve. The body is attached to the interior of the shell by muscles which can withdraw it or project it at the will of the animal; and the operculum can be drawn down upon the mouth with considerable force. It is the habit of some species, (as the Limpet and Haliotis), to attach themselves, by the expanded surface of the foot, to rocks, &c.; these are able to draw the shell closely down upon the rock, with great muscular power, just as the Conchifera draw together their valves; a short interval existing, however, when the animal is not alarmed, for the admission of water or air to the cavity of the shell. A very slight irritation will cause the animal to draw the shell close down on the rock, from which it is then very difficult to detach it.

The shell is formed, as in other Mollusca, by an exudation from the mantle; and is enlarged at intervals, in accordance with the increasing size of the animal. In some, the addition of an entire new interior layer, projecting beyond the old one, is made at every such period, as in the Conchifera; but in others the new matter is secreted only at the edge of the previous shell, and is joined on, as it were, to it; in these the line of addition is usually marked by a prominent rib on the exterior, but the interior is beautifully smoothed off.

The forms of the shell in this class vary extremely; but those which appear most widely separated may be shown to be connected by intermediate links. The open cone of the *Limpet* may be regarded as one of the simplest forms; in an allied genus, the *Pileopsis*, we find the point prolonged, and somewhat rolled upon itself; and by various links of this kind, we are brought to the regular spiral of the snail. From this we may return to the long straight form by the *Scalaria*, in which the coils of the spire touch each other only by their ribs; and by the *Vermetus* and *Magilus*, in which the commencement only of the shell possesses a spiral form, the remainder being prolonged into a straight tube. When the shell is spiral, and the point and mouth are not in the same plane, a sort of central pillar like that round which a spiral staircase is This is called the *columella*; and it is at its lower part, for the passage of water ratory organs, which are placed within the

The margin of the shell is not unfrequ with spines, as in the *Murex*; these are similar appendages in the Conchifera, by prolongations of the mantle; and the dissimilar number of them in different specimens has caused the establishment of many species, which, now that the habits of the animal are better known, prove to be but different forms of the same. For it has been ascertained that the animal has not only the power of forming new spines, but of removing old ones, especially such as would interfere with the continued growth of the shell. The edge of the mantle is applied against their bases, and a kind of absorption of shelly matter seems to take place—a notch being formed, which causes them to be easily broken off. Various analogous changes are produced by a similar action in other shells, the portions first f wholly or partially removed. Sometimes the older portion are thinned, for the purpo ing the shell; and in other cases the top o altogether removed, a groove having b around its interior, which renders it so w easily broken off: in these last cases, the viously withdraws itself from the part that separated, and throws a new partition acr

ision of this extensive class into orders, ffected by arranging the different tribes the character and position of the respi- s. The following are those adopted by

A. These are terrestrial species, adapted air by means of a pulmonary sac or air- rifice of which they can open or close at ave no shell.

NCHIATA. These, as well as all the suc- s, are aquatic, being adapted to respire s, like other Mollusca. The animals of e no shell, and they carry their branchiæ, various forms, on some part of the back.

RANCHIATA. These are similar in many respects to the preceding, but the branchiæ are situated under the margins of the mantle.

4. TECTIBRANCHIATA. In the greater part of the animals contained in this order, the branchiæ are situated upon the back or on the side, and are covered in by a fold of the mantle, and this fold usually includes a shell more or less developed.

5. HETEROPODA. This is a small order, characterised by the peculiar form of the foot, which is not spread out horizontally, but compressed vertically into a sort of fin. They carry their branchiæ, the tufts of which are generally protected by a shell, upon the back.

6. PECTINIBRANCHIATA. The animals of this order, to which belong all the spiral shells, except those of the Pulmonea, are so named from the comb-like form of their gills, which are usually situated in a cavity behind the head, corresponding with the respiratory sac of the Pulmonea. This is by far the most numerous order of the whole.

7. TUBULIBRANCHIATA. These have many affinities with the last order, but the shell is spiral only at its apex, where it is commonly fixed to (or rather enclosed by) other bodies, and is prolonged in the shape of a tube more or less regular.

8. SCUTIBRANCHIATA. In these, also, there is a considerable resemblance to the Pectinibranchiata in the form and position of the gills; but the shells are very open, scarcely in any degree spiral, and cover the body and gills like a shield; and they also differ essentially in their mode of reproduction.

9. CYCLOBRANCHIATA. These molluscs have their gills disposed in little tufts under the margins of the mantle, much as in the Inferobranchiata; but they have shells, which are spread out over the body, and differ from that order in their mode of reproduction.

Order I.—Pulmonea.

Although the greater part of the Molluscs of this order live on land, some are aquatic; but these, like the aquatic air-breathing Insects and Vertebrata, are obliged to come occasionally to the surface to breathe. They all feed chiefly upon vegetables, and many of them exclusively so; but some are extremely voracious, and will devour almost any organised matter that falls in their way. They are diffused through all climates, particular species being restricted to each. Those without a shell, commonly known as Slugs, constitute the family LIMACINÆ. In the common *Slugs*, as in most of the terrestrial species of this order, we observe a prominent head, with four tentacula, and at the end of the longer pair the eyes are situated. These tentacula can be drawn inwards, by a process resembling the inversion of the finger of a glove. On the back there is a kind of shield or disc formed by the mantle, which sometimes encloses a small shell. This shield covers the pulmonary sac, the opening of which is on its right side, and the head can be withdrawn beneath it. The *Testacella* is a kind of slug which has the disc of the mantle at the posterior extremity, and this always contains a small shell. This animal, which feeds largely on earth-worms, is abundant in the south of France, and has lately been introduced into the gardens of this country, where it is multiplying rapidly.

The *Snails* and their allies, constituting the family HELICINÆ, are closely allied to the Slugs in organisation; differing in but little else than the possession of a shell into which the body may be withdrawn. The common garden-snail of this country, and the *Helix pomatia*, or edible snail of France and Italy, are well-known examples of this family. More striking ones are to be found, however, in tropical climates; where some species of the genus *Bulimus* attain to great size, the eggs being as large as a pigeon's. In some species the direction of the coils of the shell is opposite to what it is in other spiral shells; such are said to be *reversed.* A European species of this genus is one most remarkable for the decollation of its shell. Another large snail of tropical climates, as the *Achatina*, which feeds on trees and shrubs, chiefly on the western coast of Africa, and in

the West Indies. Several of its species are distinguished by the beauty of their colours.

The aquatic Pulmonea have only two tentacula. From the necessity of coming to the surface to breathe, they can only live in water of inconsiderable depth; and they chiefly inhabit ponds and shallow streams, or the banks of rivers. Some, however, live on the sea-shore. The *Planorbis*, the shell of which is quite flat, having all its coils upon the same level, is a very common genus in this country; as is also the *Lymnæa*, which feeds upon seeds, as well as the softer parts of plants, and the stomach of which has a very muscular gizzard.

Order II.—Nudibranchiata.

The animals of this order, which might be designated Sea-Slugs, are all marine; and being adapted to breathe water at any depths, and also, in many instances, to swim with facility, they are often found at a great distance from land. When they swim, it is usually in a reversed position, the foot being turned upwards; this is made concave by muscular action, so as to serve as a kind of boat, the buoyancy of which keeps the animal at the surface without effort. This order is a very numerous one, and some of its species attain a considerable size; but, from their habits, little is known of them.

Order III.—Inferobranchiata.

The few Molluscs contained in this order differ but little from the last, except in the position of their gills, and their incapability of swimming. They are, therefore, confined to the sea-shore; where they subsist, as do the Nudibranchiata, upon sea-weeds and other aquatic plants.

Order IV.—Tectibranchiata.

This order begins to show an approximation towards that disposition of the gills which characterises the great bulk of the class; the animals composing it are marine, and live chiefly on the shore or on floating sea-weeds. A very characteristic example of the order is the *Aplysia*, commonly termed Sea-Hare, which is abundant on many parts of the British coasts. Its vernacular name is probably derived from the peculiar form of the superior pair of tentacula, which are flattened and hollowed, like the ears of a quadruped. The head has a very distinct neck. The branchiæ consist of leaflets arranged in a complex form, and situated on the back, beneath a fold of the mantle, which also encloses a flat horny shell. The digestive apparatus is very complicated; consisting of a membranous crop like that of birds, a gizzard having cartilaginous walls, and a third stomach beset with sharp hooks in its interior. These animals feed on sea-weed. They are very sluggish in their movements; but have a peculiar means of defence, consisting of a deep purple liquid, which they can discharge from the edge of the mantle when alarmed, and by which the surrounding water is discoloured, so that they cannot be discerned.

Order V.—Heteropoda.

This is a very small order; but the animals contained in it differ remarkably from all other molluscs. At the edge of the vertical muscular plate, which has been mentioned as occupying the position of the foot in the other Gasteropoda, is a small conical sucker, by which the animal can attach itself, and which represents the expanded disc of other orders. The gills are placed on the back, and close behind them are the heart and liver, which seem, as it were, external to the body. In one of the few genera which the order contains, these parts are protected by a small shell, whilst in another there is none. The body, consisting of a semi-transparent gelatinous substance, enclosed in a muscular envelope, is elongated, and generally terminated by a compressed tail; this body can be distended with [illegible]. The animal swims in a reversed position, the fun[illegible] being uppermost, and the shell depending be[illegible] they are limited to warm latitudes: one species of the Carinaria inhabits the Mediterranean, an[illegible] sionally appears on particular coasts in large nu[illegible] whilst others are peculiar to the tropics, where [illegible] the allied genera also exist. The shell of the Ca[illegible] is interesting, on account both of its extreme [illegible] and fragility, and on account of the strong resem[illegible] which that of the Argonaut or Paper-Nautilus ha[illegible]

Order VI.—Pectinibranchiata.

This order is not only by far the most numer[illegible] the whole class, but contains the animals whi[illegible] be regarded as its most characteristic examples. [illegible] have all two tentacula and two eyes, sometimes [illegible] on stalks, as in the snail. The mouth is prolon[illegible] a sort of proboscis; and the tongue is furnish[illegible] little hooks or recurved spines, which enable it [illegible] down the hardest bodies by slow and oft-repea[illegible] tion. The cavity in which the gills are fixed [illegible] the last whorl of the shell; and in some of th[illegible] there is a tubular prolongation of the mantle, [illegible] the *siphon*, for the purpose of conveying water i[illegible] cavity, so that the animal can breathe without [illegible] its shelter. By the presence or absence of this [illegible] and by the form of the shell, which here app[illegible] bear a sufficiently constant relation with that [illegible] animals, this large group may be arranged un[illegible] following families:—1. Trochoidæ, in which the[illegible] siphon, and which have the mouth closed by an [illegible] culum. Of this the common periwinkle is a cha[illegible] ristic example, though very small in proportion [illegible] pical species. 2. Capuloidæ, which have a wi[illegible] shell, very much like that of the limpets, withou[illegible] culum or notch at the margin for the passag[illegible] siphon. 3. Buccinoidæ, which have a spiral she[illegible] a canal at the end of the columella for the pas[illegible] the siphon; this is sometimes extremely prolon[illegible] in the Murex; and the genera exhibiting this cha[illegible] are all carnivorous in their habits. To this [illegible] belong the animals forming the greatest num[illegible] marine univalve shells preserved in cabinets.

Order VII.—Tubulibranchiata.

The Molluscs of this order construct an irre[illegible] tubular shell, which so much resembles that [illegible] by certain Annelida, as to be scarcely distingu[illegible] from it. They are very few in number.

Order VIII.—Scutibranchiata.

This order is also a small one, containing [illegible] principal genera, which do not differ widely fro[illegible] limpets, except in the disposition of the gills. The[illegible] are very open, without an operculum, and the g[illegible] number are not in any degree spiral. In the *Ha*[illegible] the shell is slightly twisted; and from a fanci[illegible] blance it is thought to bear to the ear of a quad[illegible] it has been called the Sea-Ear. This animal, [illegible] living state, is one of the most beautiful of Gaster[illegible] on account of the variety and richness of its co[illegible] Its shell, when the surface is polished, posse[illegible] pearly lustre, with resplendent metallic hues. [illegible] consequently much sought for as an ornament.

Order IX.—Cyclobranchiata.

The general form of the *Limpets*, which prin[illegible] compose this order, is well known; and the pecu[illegible] in the position of their gills has already been men[illegible] Closely allied to the limpets in general structur[illegible] differing remarkably in the formation of the she[illegible] the *Chitons*, of which some small species inhab[illegible] shores, but which attain to much greater size be[illegible] the tropics. Their shell is composed of a num[illegible] plates arranged behind one another with great r[illegible] rity, and connected by a very complex series o[illegible] ments and muscles, which reminds the nature[illegible] those which unite and move the different segme[illegible] the articulated animals.

CLUDED).

f the interior surface of each valve. In some
ifera, this muscle is single, and in others it is
, the two parts being even at opposite ends of the
Upon this character it has been proposed to
the primary division of the class into orders; but
ssification thus formed is not a natural one, in-
h as it brings together kinds which have little re-
ance, and widely separates others which are
allied.
order to describe the general structure of the
ifera, it will be advantageous to select some par-
r illustration; and the common *mussel* is well ad-
to this purpose. On opening such a shell, it is
hat the two valves are lined by a membrane which
pends with the tunic or *mantle* of the Tunicata.
s divided into two halves along a considerable
f the edge of the valves, but is united near the
end. In some Conchifera, as will be presently
d, the two halves of the mantle are separated
their whole extent; whilst in others, as in the
ata, they are completely closed, with the exception
two orifices for the ingress and egress of water,
are sometimes drawn out into long tubes. In the
), the water enters through a slit in the closed
f the mantle, and passes out by another in its
ourhood; but the water thus introduced is prin-
for the supply of the gills, as the mouth, or en-
to the stomach, is placed at the small end of the
where the mantle is quite open, and can take in
from the surrounding water, which comes into
ntact with it. The gills in all Conchifera consist
r riband-like fringes, fixed to the mantle along
ge of the shell most distant from the hinge. Near

r of Mussel: a, right valve; b, left valve; c, hinge; d, ste-
; e, tentacula; f, foot; g, byssus; h, branchial orifice;
t; k, termination of intestine; l, liver; m, gills; n, adduc-
muscle; o, ovarium.

all end of the shell is seen the stomach, with the
tube leading to it, the orifice of which is surrounded
our tentacula or feelers. To the right of this is
he long and complicated intestinal tube, with the
lying in separate masses amongst its folds.

nearer the large end, the cavity of the shell is chiefly occupied by the ovarium, in which the eggs are formed. Close to this is the powerful adductor muscle, by which the valves can be drawn together with considerable force. The intestinal tube is seen to terminate near the opening at the posterior (or right-hand) extremity of the shell, which discharges its contents, and serves for the exit of the respiratory current.

The foregoing description will apply, with slight variations, to the structure of almost all Conchifera; but we have now to notice two organs, which are absent in some, and in others more largely developed than in the present instance. From the lower part of the shell, passing out between the separate edges of the mantle, is seen the *foot*, a fleshy muscular organ, somewhat resembling the tongue of higher animals, and not containing any hard support, or being protected by any envelope. This foot, which is the only special locomotive organ possessed by the Mollusca of this class, serves a great variety of purposes, sometimes enabling the animal to leap with considerable agility along a hard surface, sometimes being used to bore into the sand or mud, and sometimes serving only to affix the animal to some firm support. From the base of this foot there proceeds, in the mussel, a band of hair-like filaments, forming what is called the *byssus*. These sometimes exist in great abundance, and serve, by being fixed by their extremities to the shore or bottom of the sea, to anchor the shell, and yet to allow the animal considerable freedom of motion within certain limits. Frequently the byssus is altogether absent.

The Conchifera have usually more power of locomotion than the Tunicata. Some of them, however, as the oyster, are attached to one spot during all but the earliest period of their lives. Others adhere by the byssus, or by the foot, by which they obtain a certain range; and others are free during the whole of their lives, swimming and leaping with considerable agility. In these movements some of them appear to be directed by powers of sight, and in these are perceived small red spots at the edges of the mantle, which are believed to be eyes. They do not appear to have much choice of food, nor are they provided with any other means of obtaining it than the ciliary action, which introduces constant currents of water into the mouth. In general they do not attain any great size, but they are on the whole larger than any Molluscs except the Cephalopoda; and a few species attain considerable dimensions—a *Pinna* having been known four feet long, and a *Tridacne* (Giant Clamp-shell) having been known to weigh 600 lbs. They are distributed over the whole globe, principally frequenting the shores or shallows. Each region has certain species peculiar or most abundant in it, and there are few which are not limited to one hemisphere. The temperate zone appears as favourable to the development and multiplication of some species as the torrid zone to others; but the largest kinds are only found in warm latitudes.

In the subdivision of this class into orders, the degree in which the two lobes of the mantle adhere along the margin of the shell, is the character chiefly rested on; the presence or absence of the foot, and of the byssus, also, are important characters; and along with these the structure of the hinge should be attended to. On these grounds, the five following orders are established by Cuvier:—1. Ostraceæ, the *Oyster* tribe, in which the two halves of the mantle are separated the whole way round, or the foot absent or very small: they are usually fixed by the shell to solid bodies. 2. Mytilaceæ, the *Mussel* tribe, in which the mantle remains open in front (at the end where the mouth is situated) and closed behind, an aperture being left for the egress of the fluid. They have a foot strong enough to crawl by, and commonly affix themselves by a byssus. *3. Chamaceæ, or Clamp-shells*; in these the mantle is closed, with the exception of three apertures, two of which are for the ingress and egress of water, and the third for the passage of the foot, which is here usually more powerful. 4. Cardiaceæ, or *Cockle* tribe, in which the mantle is not only closed, but extended at spiratory apertures into tubes of greater or les The foot is very strong. 5. The Inclusa, in wh mantle has only one opening for the passage of t at the posterior end it is prolonged into tubes length, that can be extended far beyond the sh the common *Solens* or Razor-Shells.

Order I.—Ostraceæ.

The Ostraceæ, of all these orders, exhibit the approach to the Tunicata, both in the absence foot, the entirely fixed condition of the body, an low grade of their organisation in general. T itself is usually fixed by adhesion to other ma a few, the animal is attached by a byssus; a species, which are unattached, have a slight p changing their place, by suddenly closing the and squirting out the water that was between t the true *Oysters* there are no teeth in the hing is held together by the ligament only. Several exist, some of which are as abundant in tropical as the common Oyster of temperate seas is on th of Britain. Their continued abundance, notwi ing the large quantities constantly being cons less surprising when we reflect upon their ast fertility, as many as 1,200,000 eggs having b tected in a single individual. The *Pectens* have like that of the Oysters, but differ in having the of the valves raised up into ribs, and in hav angular projections, commonly termed ears, sides of the hinge. Many of them are very c coloured, and they are the most active of th order, being entirely unattached, and swimmi greater quickness than would have been expect their imperfect means of locomotion.

The foregoing tribes of Ostraceæ, and man which might be enumerated, are distinguished presence of only one adductor muscle; in the re of the order, as in most other Bivalves, there second. Among these may be first mentio *Etheria*, which is a sort of fresh-water oyste *Aviculæ*, which furnish the greater number of th so highly prized as ornaments, are commonly *Pearl Oysters*, from their general resemblance same tribe. The valves are extended into ears o on each side of the hinge; and these are frequent long on one side. The pearl is produced from th substance as that which lines the shell, and w commonly known as mother-of-pearl. It seems to result from some irritation of the mantle, causes it to excrete an unusual quantity of pearly at one spot; and grains of sand, or other small pa which, by getting between the membrane and th seem to have caused such an irritation, are often in the centres of pearls. Sometimes, again, pe found at points where the shell has been pierce boring animal; and it has been proposed to ca formation of pearls by perforating the shell; b pearls so produced seldom have that regularity form which is as important to their value as size. Pearls are also produced within many other The *Pinnæ*, or Wing-shells, approach the Mu many respects; they are remarkable for the len silky character of the byssus by which they attac selves to rocks, and which is collected in the M rranean for the manufacture of gloves and other for which it is well adapted by its strength an bility.

Order II.—Mytilaceæ.

The order Mytilaceæ is well represented by t mon *Mussel*, which has been already describe various species of this group are extensively d and from their abundance in particular localiti their palatability, they serve as important art food. Belonging to this order are some rem boring shells, which have the power of penetrati rocks, and making deep holes, which are enlarged advance, in accordance with the growth of the

ı, therefore, they cannot quit. By what means mplish this is unknown. The flattened form ll is a sufficient proof that it is not by mecha- on, as in some of the boring shells of the order

The *Anodon* is a fresh-water mussel, closely general conformation to those inhabiting the liffering remarkably in the absence of teeth in , whence the name of the genus is derived. is another fresh-water genus, having a more ed hinge. It is remarkable for the pearly the lining of the valves, and for producing arls, sometimes in considerable abundance. not so pure in their colour, however, as those icula, and are but little esteemed. Some spe- nio are common in the lakes and rivers of ut the greater number are peculiar to North ; many of these are remarkable for their size ır. There are some marine Mytilaceæ allied ios, one of which burrows in coral.

Order III.—Camaceæ.

der Camaceæ includes but a comparatively nber of species, most of which are peculiar to limates. The most remarkable is the *Tridacna* Giant Clamp-shell, of the Indian Ocean. When is animal attaches itself to rocks by means of ous foot, which serves as a sort of byssus; but shell becomes so massive that it is in no danger , it detaches itself, and the groove of the shell p. These animals, with their shells, sometimes e weight of many hundred pounds. Smaller s are often brought to this country; the valves d to receive water from small fountains, &c.; he continent, they are employed as reservoirs ater in the churches. The foot has a structure that, to separate the shell attached by it, it is to chop it with a hatchet like a cable.

Order IV.—Cardiaceæ.

animals of the order CARDIACEÆ, or *Cockle* usually find greater activity than in any others ss. The foot now comes to be a very impor- ın, possessed of great muscular power, and f being applied to a variety of uses. Many of mals bury themselves in sand or mud; and it e that we find the respiratory orifices prolonged es. In the common Cockle, however, these ı scarcely be said to exist, the orifices not being l beyond the shell. Its foot is very large, and ent nearly double in the middle; by doing this, suddenly straightening it, the animal is enabled considerable leaps. The hinge is very beauti- structed; and the two valves lock closely to- The *Trigonia*, a very interesting genus, abun- ormer ages of the globe, but now restricted to es of New Holland, seems allied to the cockle tructure of its hinge and shell, in the size of and in its general organisation, although its ı divided into two lobes along the whole margin lves, as in the oyster. This is an instance of opriety of basing our classification on any single rs. There are other Cardiaceæ which obvi- nduct towards the next order. Such is the of which the valves, when closed together, gape sterior extremity; and through this passage es out two long tubes which terminate in the l orifices and funnel. These tubes have an ructure, and can be entirely drawn within the These long tubes are seen also in the *Venus* and , of which one species is remarkable for the ies which guard its posterior end; and also in *tra*, and the animals allied to it. In some cases s are united along their whole length, and ap- e single; but they are always in reality double. animals are in the habit of burying themselves ir mud, or in stones; and the tubes serve to s fresh water from the entrance of their bur-

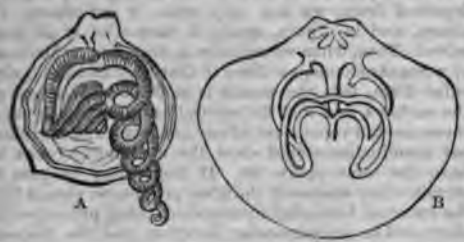
Order V.—Inclusa.

In the order Inclusa we usually find the valves, when joined together, presenting more or less of a cylindrical form, as in the common Razor-shell. A hollow is left at each end, and from one the foot is projected, through a passage in the mantle, whilst the other gives exit to the respiratory tubes, which are often prolonged to a great length. The animals live almost uniformly buried in sand or mud, in rocks or wood. The *Solen*, or Razor-shell, is a very characteristic example of the order, which contains, however, some forms that depart very widely from it. The foot, which can be projected from the lower end, is firm and pointed, and serves as an admirable boring instrument, by the use of which the animal can burrow in the sand with great rapidity, sinking very deep when alarmed. The *Mya* approaches, in the form of its shell, and in its general organisation, to the previous family; but some of its species also closely approximate the Solens. The *Pholas* is a very interesting genus, the animal of which nearly resembles that of the Solen, whilst the shell is formed of several pieces, and would thence be called a *multivalve*. There are two principal portions, and a variable number of accessory pieces. Some species of this genus bore in mud, others in rocks, and a few in wood. Their action seems purely mechanical. They fix themselves firmly by the powerful foot, and then make the shell revolve; the sharp edges of this commence the perforation, which is afterwards enlarged by the rasp-like action of the rough exterior; and though the shell must thus be constantly worn down, yet it is replaced by a new formation from the animal, so as never to be unfit for its purpose.

We now pass on to some very remarkable forms of this order, in which the bivalve character of the shell gradually disappears, being replaced by a new structure of which no examples have been yet seen. The *Teredo*, or Wood-worm, as it is commonly termed, is an animal of the same general organisation as the Pholas; but its valves are smaller in proportion to the body, and its tubes still more prolonged—at least when the animal may be regarded as full-grown. By means of the mechanical action of its valves, it perforates timber, in the same manner as the Pholas penetrates stone. As it advances, the respiratory tubes are prolonged, so that their orifice remains at the entrance of the burrow, which is very small in proportion to the cavity formed by the animal as it increases in size. This orifice is furnished with a pair of valve-like shelly plates, termed *palmulæ;* by the action of which a current of water is driven towards the body of the animal, in order to serve for its respiration, and at the same time for the supply of its food. The gallery is lined by a calcareous exudation from the surface of the tubular prolongation of the mantle, which forms a kind of secondary shell. The Teredo is an animal extremely destructive to timber, especially in warm climates, from which it seems to have been originally introduced into the seaports of Europe. In other genera the valves are lost in the shelly tube, so that the ordinary structure of the class is no longer apparent.

Besides the orders now described as composing the class Conchifera, there is a very curious group which should also be included in it, although established as a separate class by many naturalists. This is the group of BRACHIOPODA, containing only three genera at present known, namely, *Terebratula, Lingula, and Orbicula;* but formerly of much greater comparative importance. These animals have all bivalve shells, differing in no essential particular from those of the Conchifera in general. The two former genera are attached, however, by a footstalk proceeding from an opening in one of the valves near the hinge, to solid substances; and in this respect they have an affinity with the Tunicata. The Orbicula is attached, like an oyster, by one of its valves. They bear considerable resemblance to the Tunicata, also, in the structure of the nutritive system—the digestive apparatus, heart, gills, &c. But

in the complexity of the muscular apparatus provided for giving motion to the valves, they much surpass the highest of the other Conchifera. There are not only several muscles provided for the closure of the shell, but another set to open it—an organisation which no other Bivalves possess. The most peculiar part of their structure, and that from which they derive their name, consists in the presence of two very long arms or tentacula, between the origin of which the mouth is situated. These can be projected to a considerable distance from the shell, or drawn in and coiled up spirally within it. They do not appear, however, to seize upon prey; but rather, by means of the cilia with which they are fringed, to create currents which may bring food to the mouth. In the Terebratula, these



Terebratula:
A, valve with the spiral arms; B, valve with arms removed.

arms are affixed at their bases to a very curious framework within the shell, the use of which is uncertain; but it is believed to aid, by its elasticity, in separating the valves from each other. This framework is most complex in the species in which the arms are shortest. The species of Brachiopoda at present known, live at great depths in the ocean; and many of their peculiarities seem to have reference to that particular condition. They are distributed through all latitudes.

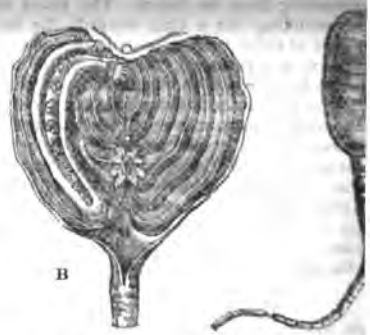
CLASS XVIII.—TUNICATA.

The lowest and simplest of the molluscous classes is that to which the name of Tunicata has been given, in order to mark the peculiar structure of the animals composing it. They bear a general resemblance to the animals which form bivalve shells, but are of inferior organisation. They are peculiarly distinguished from them, however, by the entire absence of any shelly envelope; and by the possession, instead of it, of a *tunic* or external coat, of greater firmness than the rest of the structure, which surrounds the whole body and affords it protection, besides being the medium of its attachment to the fixed substances upon which these animals usually rest. This external tunic is extremely variable in colour, consistence, and form. Sometimes it is dark, and of leathery toughness; sometimes even cartilaginous; and in many species it exudes a glutinous matter, by which particles of sand, gravel, comminuted shells, &c., are attached together, so as to form an additional envelope, which possesses great firmness. Sometimes, on the other hand, the whole body is extremely soft and delicate in its structure, and the tunic is a thin transparent membrane, the colour of which depends upon the intensity of the light transmitted through it.

The greater number of the animals of this class are attached, during the principal part of their existence, either to each other or to solid bodies. In a few species, a number of individuals are united by a stem which contains vessels establishing a connexion amongst them all; so that they closely resemble the compound Polypifera. More commonly, however, the Tunicata live in societies, each individual being distinct from the rest, but a number adhering together to form one mass, which is often enclosed in a common envelope. In other instances, each animal is completely separate from the rest, although a number are found in the same locality. Where this is the case, the animals are severally fixed to rocks or other solid masses, either by the of the tunic itself, or by a sort of footstalk from it.

The *tunic* is always provided with two orifi are sometimes placed near each other, and times at the opposite extremities of the body. these orifices serves for the entrance of wate cavity of the mantle, the other for its exit. bulk of the body may be considered as a re chamber, that is, a cavity lined with a membr which the blood is plentifully distributed, in o it may be exposed to the action of the air ent the water introduced into it. Accordingly, a current of water is maintained by the action of (minute, constantly vibrating, hair-like filamen clothe the lining membrane; and this curr serves to supply food to the inactive creatu produces it. The true mouth, or entrance to that leads to the stomach, is situated at the b the *branchial sac*, or respiratory chamber; an the water introduced into the latter passes stomach, and after traversing the intestinal c parting with whatever nutritive materials it e is ejected from the second orifice of the tunic, stream that has merely passed over the re membrane.

In these actions nearly the whole life of cata appears to consist. Those which are a rocks have no power of changing their place attached; and those which float in water, ei or adherent to one another, seem to have n locomotion, except what they derive from th just described. The only other movement noticed, is the contraction of the whole sac, w place when the animal is irritated in any water contained in it being violently ejected.



Ascidia Australis: A, external aspect; B, interna

The accompanying figure will give a gen the structure of one of these animals. O hand it is seen in its natural condition, with footstalk; the two projections on the righ short tubes terminating in the orifices by w is introduced and expelled. On the left hav the interior of the sac, which has been laid seen to be nearly empty, the intestinal canal side occupying but a small proportion of and the membrane lining it is disposed in fo are traversed by blood-vessels, so as to greatest extent of surface to the action of by the air contained in which the vital fluid The orifice by which the water enters this called the *branchial* aperture, because it is the admission of water to the *branchiæ*, or that through which it passes out is called th vent.

The division of this class into orders is ma torily based upon the relative position of orifices, which have a close relation with th life of two groups of animals respectively ASCIDIÆ, the two orifices approach one an

ngth of which varies from five to fourteen inches, tremely vivid.

SUB-KINGDOM—RADIATA.

e general fact, that, in every complete natural p, there are some members which exhibit most ly its characteristic peculiarities, whilst there are s in which these cannot be distinctly traced, or are ether obscured, is nowhere more evident than we compare together the different classes which associated into this sub-kingdom. For whilst in we find the *radiated* arrangement of parts almost ably preserved, and, if left at all, only slightly rted from, we can only trace it indistinctly in s, and in others, again, it cannot be at all per- d. Thus, when we examine a Star-Fish, a Mollusk, Sea-Anemone, we observe that they all have a cir- r form, that the mouth is in the centre of one of urfaces, and that the several parts arranged round are but repetitions of one another; and an inter- examination would shew the contained organs to the same character. If from these we pass to ain other species of the same groups, we should find external form slightly modified, being prolonged or toned in one particular direction, and the disposi- of the interior organs no longer radiated. Again, e Sponges, all trace of a circular arrangement of s disappears. Yet these, and other groups in which radiated type is equally absent, must be associated the classes more characteristic of it, on account of general conformity of structure, and in some in- ces their very close alliance with them.

oreover, in comparing the different forms of this p, we see exemplified another general principle, ely, that the *aberrant* members of it—those which rt most widely from its regular type—connect it other groups. For, among the species in which radiated arrangement is obscure, we find some that lost us towards the Mollusca, and others that lead o the Articulata; whilst in the Sponges and Coral- we have an evident approximation to the vege- e kingdom. So close, indeed, is this approximation, there are many beings of which the true character t in doubt; they live, and grow, and multiply, very h in the manner of plants, and it cannot be ascer- ed with certainty whether the feeble motions they hibit are to be regarded as spontaneous or not.

he great diversity, not only in form, but also in de- of organisation, that exists amongst the Radiated es, prevents much being stated of their general acters that shall be applicable to all of them. Thus, ough the skeleton is external in some species, as Sea-Urchin and Star-Fish, it is internal in others, he Corals and some of the Jelly-Fish. Although of them have a distinct mouth and stomach for reception of aliment, others imbibe it, like plants, by absorption through their exterior. Although e exhibit a high degree of sensibility, others are so hetic as scarcely to manifest any feeling of injury n severely wounded.

he class POLYPIFERA, containing the coral-forming nals, may perhaps be regarded as the most cha- eristic of the group. These animals usually asso- themselves together into compound masses, of h every part is capable of existing independently e rest, and each polype exhibits in itself the radi- structure, which cannot be detected in the entire s; but all have a certain degree of connexion with other, which may be compared to that existing ng the different buds of a tree. Even the species h do not form solid structures, such as the Sea- mone, remain almost constantly attached to the e spot.

he ACALEPHÆ, commonly termed Sea-Nettles, or y-Fish, have no such tendency to aggregation, and never attach themselves to solid bodies, but wander arge through the ocean. By these characters, and

by their extreme softness, these animals are readily distinguished.

The ECHINODERMATA also live solitarily, and have the power of free movement, except in a few species which approach the Polypifera; but they are readily distinguished from the Acalephæ by the density of their texture, and especially by the roughness of the integument, which is usually beset with prickles or spines, as in the Star-Fish and Sea-Urchin.

In the two following classes, no distinctly radiated structure can be seen:—

The POLYGASTRICA, which are ordinarily known as Animalcules, are beings of extreme minuteness and general simplicity of structure. In the absence of distinct organs for the various purposes of the economy, they correspond with the lower Radiata, but they differ in the extreme activity of their movements. A separate division of the animal kingdom might almost be formed for them alone, so difficult is it to assign them any place in the ordinary scale. Some of them exhibit a tendency to associate into compound structures, like the Polypifera.

The PORIFERA, or *Sponge* tribe, are of all animals those which approach nearest to plants, in the absence of the characters peculiar to the kingdom in which they are placed, and in the want of definiteness of form. Certain movements exhibited by them, however, and their close affinity with some of the Polypifera, render it proper that they should be classed among animals.

CLASS XIX.—POLYGASTRICA.

This class includes the greater part of those minute beings termed *Animalcules*, which have been, from the time of the discovery of the microscope, such fertile sources of wonder and delight, both to those who have themselves observed them, and to those who have heard from others of their marvels. Previously to that epoch, it was not suspected that beings existed of such minuteness as to be invisible to the eye, much less was any idea entertained of the extreme smallness of many species; and still more improbable and absurd would the statement have been deemed, that such beings are not of rare occurrence, but abound in every drop of stagnant water, and even exist in the whole mass of the ocean. Yet such has been shown to be the fact, and every improvement in the powers of the microscope has enlarged our ideas of the extent of animal life in the fluids of the globe; so that the philosopher is now ready to admit no limit to the possible minuteness of living beings, but looks to still further improvements in the microscope as a means of extending his acquaintance with them, and not as likely to set any bound to his inquiries.

Animalcules may be obtained without difficulty for microscopic examination during the warmer part of the year, by skimming the surface of ponds, especially those in which the water exhibits a red or green tinge, or in which it is covered with duckweed, or with the slimy film which may often be noticed. Many curious species frequent these situations; but the commoner ones may be obtained with even less difficulty, by placing soft vegetable matter, of almost any description, in vessels with water, and exposing the mixture to the sun and air for a few days. As soon as decomposition begins actively to take place, Animalcules may be detected in the fluid, and in a short time they often crowd it most densely. These are generally at first of a simple kind; but new species soon prevail, and those first seen disappear. Different kinds of vegetable matter seem to favour the development of the different species; and there are some Animalcules that can be produced in no other way than from an infusion of some particular substance. Asparagus stems that have been boiled will favour the production of Animalcules, with perhaps as much readiness as any vegetable matter; hay, chopped straw, the leaves of plants, and other common ingredients, may also be advantageously employed.

In the class Polygastrica are included all the most minute species of true Animalcules, and s
the larger ones; but as a whole, the beings
it are smaller than the Rotifera, and far s
those of any other class. The largest amon
but with difficulty seen by the naked eye,
dimensions of the smallest the mind can scr
an adequate conception, although they ma
rically stated. The class takes its name fro
entertained by the celebrated Prussian natu
renberg (who has devoted almost his whole

* larger species more than 180 millions are estimated nly a grain.

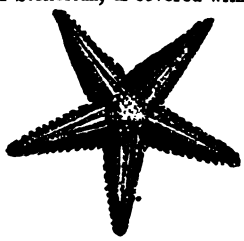
CLASS XX.—ECHINODERMATA.

The class of Echinodermata, comprehending those well-known animals, the *Asterias* (Star-Fish), and *Echinus* (Sea-Urchin), takes its name from the prickly skin with which most of the tribes it includes are provided. But this is not an universal character; for some of the species, which border upon other groups, have a skin destitute of any appearance of spines. There is little difficulty, however, in distinguishing the animals of this class from all others, for in nearly the whole of them the radiated structure, or the arrangement of parts in a circular form, is very evident; and they are the only animals among the Radiata which have the power of moving from place to place, and have at the same time an integument firm enough to resist pressure.

Although the character and degree of organisation in the different subdivisions of this class may be regarded as about the same, the form of the organs, and the mode in which they are arranged, are very different, so that it will be better to describe each group separately. The class may be distributed into three orders; the Stellerida, including the Star-Fishes and their allies; the Echinida, including the Echinus and its allies; and the Holothurida, a group less commonly known, and differing much from the others.

Order I.—Stellerida.

The common *Asterias*, or Star-Fish, which may be taken as a type of the order Stellerida, is covered with a tough leathery skin, beset with prickles. The animal has the form of a star, with five or more rays springing from a central disc. In the middle of one side of the disc is situated the mouth, and this side, according to the usual habits of the animal, must be considered the lower one. The mouth opens into a globular stomach, which sends out prolongations into the several rays, but there is no intestine in this animal, nor any second orifice to the digestive cavity, so that the indigestible parts are rejected by the mouth, as in the Sea-Anemone.



Asterias: upper surface.

If the tough prickly skin be removed, it is seen that it is supported by a series of bony plates, beautifully jointed together. Along the under side of each ray, the plates exhibit a series of perforations, through which there issue, in the living state, a large number of minute tubes, which may be occasionally seen projecting on the outside. These tubes are termed the *feet*, on account of the use to which they are subservient. Every one of them is connected, on the interior of the shell, with a small vesicle or bag, which is capable of being distended with water by a system of vessels adapted to the purpose, and of contracting so as to force its contents into the tube. The tube consists of a delicate elastic membrane, covered with two layers of muscular fibres, the one circular, the other longitudinal, and furnished with a sucker at its extremity. When distended with water, the tube projects from the body; and, if the sucker be then applied to any moveable substance, it will be drawn towards the body by the elasticity of the membrane, when the distending force is relaxed. Although each sucker is small and weak, the combined efforts of many give the animal considerable power, not only of drawing prey towards the mouth, but of moving its own body from place to place.

The order Stellerida includes a large number of forms, having a general resemblance to the *Star-Fish*, but differing much in the relative proportion of the body and rays. Thus, in some species, the arms seem to make up the entire animal, no central disc being present, save that formed by their union. In others, the arms appear simply appendages to the central disc, to which the stomach and other important organs are

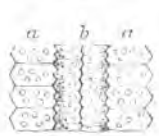
confined. In some instances, the arms send off lateral appendages; and these occasionally again subdivide, so that a branch-like structure is produced, such as we find in the *Comatula*.

A very remarkable tribe, included among the Stellerida—once a group very important in its numbers, and in the extent of its diffusion through the sea, but now presenting only two or three comparatively small species—is that known under the name of *Crinoidea*, or lily-like animals. These are formed much upon the plan of the Comatula, but they are attached by a jointed stalk to solid substances, usually to the bottom of the sea. They thus remind us of the Polypifera, which they seem to connect with the Echinodermata. This group contains two principal subdivisions—the *Encrinites* and the *Pentacrinites*. The former are distinguished by the roundness of their stems, the joints of which being flat and perforated in the centre, are known under the name of wheel-stones, or St Cuthbert's beads. The latter have pentagonal stems. The former seem to have been the most ancient.

Order II.—Echinida.

In the Echinida we find the body usually of a somewhat globular shape, and enveloped in a firm shell, composed of a very regular series of plates jointed together. In the Echinus, the shell of which is commonly known as the Sea-Egg, we observe two orifices situated at the poles, as it were, of the globe. The larger of these orifices is the mouth: at the smaller one the intestinal tube terminates. The mouth, as in the star-fish, is generally directed downwards. It is furnished with a very curious apparatus of teeth, which are worked by powerful muscles, attached to projections of the shell, that may be seen on the inner margin of the mouth; and their points can even be protruded beyond the mouth, so as to lay hold of prey brought to them by the long tubular feet. By the action of the teeth, the food is ground down before it passes into the intestinal tube, which is here of considerable length, and takes a couple of turns round the shell before its termination. Round the second orifice of the shell are disposed the ovaria, which are very largely distended with eggs at some seasons, and are eaten under the name of the *roe of the sea-egg*.

It is the exterior organisation of these animals, however, that presents us with the greatest sources of interest. On looking at the Echinida in their living state, we see that most of them are covered with spines of considerable size, instead of with such small prickles as the Asterias bears. Moreover, these spines are seen to be moveable at their bases, and their power of motion is due to their peculiar connexion with the shell. Each spine is spread, at its root, into a cup-like form, and the hollow of this cup fits upon a little knob or tubercle projecting from the surface of the shell, so that a complete ball-and-socket joint is formed. The spines are connected to each other, and held on the shell by the skin which covers the latter, and which is attached around their roots; and it is by the contractions of this skin that they are moved.



Shell of Echinus: *a*, tubercular plates; *b*, ambulacral plates.

On looking at the exterior of the shell of an *Echinus*, it is seen that the tubercles are arranged with great regularity, and that the larger ones are confined to particular rows of plates, which are hence called *tubercular* plates. Between these are smaller plates, commonly bearing smaller tubercles, and perforated with a number of minute holes, for the passage of the tubular feet; these are called *ambulacral* plates. The *tubular feet*, like the spines, are *much longer* than in the star-fish. They are always capable of being projected beyond the spines; and, taking an attachment by the s their extremities, they can cause the shell to were, upon the points of these. In some sp spines are five or six inches long, whilst the of the body is much less. The tubular feet of notice on account of their transparency; an mal appears to be walking upon its spines, merely resting upon them as fulcra, and dra forwards by these curious organs. It is to b bered that the body will weigh much less in w in air, and thus may be supported upon spin delicacy.

The structure of the shell itself, and the m increase, are not among the least interesting the history of this animal. The shell is com already stated, of a large number of plates disp great regularity, and accurately fitted together plates are usually of an hexagonal shape, b large and small ones join, there is of course s fication. Now, it is obvious that a shell of glob can only be regularly increased in all its dime the equal growth of every part of it. This is provided for by the interposition of a thin layer brane, from which the shelly substance may sited between the edges of all the plates; membrane also answers the purpose of formin nexion between the skin covering the shell an gans of nutrition within.

These animals are generally found on sandy and especially in little nooks secluded from t influence of the waves. Some of them excavat in the sand by means of their spines, and ca even works its way into solid rock. Their foo mixed quality. Fragments of shells, Crust other marine animal products, are found in t machs, as well as portions of sea-weed. Th their prey whilst lurking in their hollows, by their tubular feet to play loosely in the water and when any small animal touches the suck end of one of them, it is soon secured by the s of others, and drawn within the range of the teeth.

It is not in every species of Echinida that bular form is so well marked as in the Sea-Eg are many in which the shell is more or less and in which one or both the apertures of th tary canal are out of the centre. In these t apparatus is either absent or comparatively f

Order III.—Holothurida.

In the last order of Echinodermata, the Ho we find the characters of the class remarkabl with those of Articulated animals. The bo enveloped in a hard shell, but in an elastic sk tute of spines or prickles. It retains, in som the globular form, but in many it is very m longed, so as to be almost cylindrical, and s semble that of the Worm tribes; and it is of even marked by transverse bands, indicating into segments. Still, however, a distinct conformation may be seen around the mouth of these animals look as if a star-fish were set on the body of a large worm. In the gener mation of the internal organs they correspon Echinida; but they are in some respects more and the respiratory organs are constructed plan of those of the Articulata. They thus fo interesting link of connexion between the Ra Articulated sub-kingdoms.

The skin of most of the Holothurida is so v that they can change their size and form in able degree. They are capable, too, of swim considerable rapidity, and some of them slugs upon solid surfaces. Small species are o found in British seas; but on some tropical s are very abundant, and grow to the length or twenty inches. They are sometimes ea poor on the Neapolitan coast; but in the M pelago they are regularly sought, and con

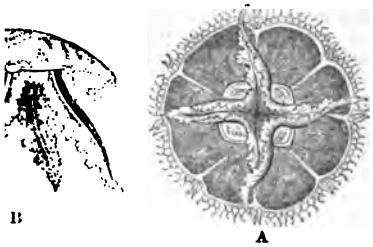
ket, where, under the name of *trepang*, they price.

CLASS XXI.—ACALEPHÆ.

e of the class next to be described, the derived from the stinging power possessed l the animals composing it. The word is erm for *nettles;* and by the designations *tang-fishes*, &c., these animals are popularly ell as by another, also expressive of a cha- hich the group is distinguished—*jelly-fish.* difficult to give any description of the struc- class that shall include all the members of do they vary among each other. They all he Polypifera in being unattached to solid having the power of freely moving through d they differ from the Echinodermata in overed with a dense integument. Their ness is one of their most remarkable cha- me of them attain considerable size, yet ost entire absence of any hard support or indeed, it is only in a few species that any

es of the Acalephæ are so soft, that they like masses of jelly; whence originated n name. They consist of a sort of network aments, the interspaces between which are h water; and so large a proportion does at it drains away when the animal is kept ment for a short time, leaving but a thin brane behind it.

gement of the mouth, stomach, and other ubject to great variation in the different of this class, and we here encounter the able fact, of the existence of animals of ucture and varied powers, which do not regular mouth, but imbibe their food like t-like filaments. Owing to the difficulty of ie structure of beings which can be so im- served, however, the organisation of many curious species is as yet very imperfectly and it will be better to confine ourselves onsideration of those most certainly known. commonest forms of this class is the *Me-* is often seen floating in vast numbers on days at a little distance from the shore. consists of a large umbrella-shaped disc, ler surface of which hang down four broad tacula. Both disc and tentacula exhibit a ul assemblage of colours, like those of the en the rays of the sun are reflected from . On the under side of the disc is seen the ted in the centre, and surrounded by the tentacula. This is the entrance to a sto- lies in the middle of the disc, and is sur- four ovarial chambers, having separate



B A

nder surface, showing the mouth in the centre, sur- he tentacula, and the ovarial chambers exterior to these; B, side view, showing the tentacula hang- their natural position.

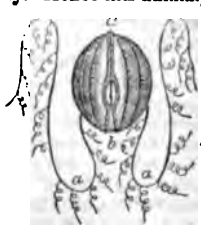
ices. The animal may thus be compared, ve, to a Sea-Anemone detached from its vimming with its mouth downwards. The f the disc extends much beyond the sto- arial chambers (which may be described as occupying the part corresponding to that included between the metallic stretchers of the umbrella), and this broad free margin is endowed with muscular powers, and performs a series of regular undulations, by which the animal is propelled through the water.

The extreme softness of the tissues of these *Medusæ* is an obvious reason why they should not expose themselves to the rough surface of the ocean, where they would be beaten to pieces by the waves—or to the proximity of the shore, from which they would soon receive fatal injury. Although so soft, however, they have the power of mastering prey of much firmer structure, and hard Crustacea, as well as other marine animals of high organisation, supply them with food.

The *Medusa* shares in another property possessed by most of the class, that of luminosity or phosphorescence. It is chiefly to the smaller tribes, accumulating in immense numbers, and so transparent as to escape notice by day, that the occasional phosphorescence of the sea is due. This very beautiful phenomenon may be seen not unfrequently on the shores of Britain; but it is most splendid in warmer seas, especially in the Mediterranean. In the midst of the diffused luminosity, caused by the glow of innumerable multitudes of small Acalephæ, and even of animalcules far smaller, the larger ones shine out like stars in the milky-way. The cause of this beautiful appearance is ill understood. It has been ascertained to exist in a secretion formed from the surface, which can be washed off, and can thus communicate the phosphorescence to various fluids, in which it seems to remain until decomposition has taken place. The light is rendered more brilliant, when exhibited by the animal itself, by any thing which irritates it; and this fact is observed in the case of most luminous animals.

An interesting species, allied in general form to the Medusa, but differing from it in a remarkable particular, is the *Rhizostoma* (root-mouth). No mouth is seen in the centre of the inferior side of the disc, but the stomach sends canals into the substance of the tentacula, which terminate in a number of minute pores at the extremity of those organs. By these small pores, as by the roots of plants, nourishment is absorbed into the system, for the ends of the tentacula fix themselves like suckers upon the surface of the animal they have grasped, and imbibe its juices. These and other Acalephæ which move through the water by the undulations of their membranous disc, are included in the order PULMONIGRADA. All the Acalephæ of this order exhibit a very regular disposition of their parts around a centre, so as to be truly *radiated* animals. Some of them attain a diameter of two or three feet.

Another interesting species of this class is the *Beröe pileus*, a small animal not unfrequently found on the coast of Scotland. When at rest in the water, it looks like a bright globe of jelly, about half an inch in diameter. An opening is seen at each pole of the globe; one of these is the mouth, and at the other the alimentary canal, which runs straight across the body, terminates. Its surface is marked by eight bands, running, as it were, from pole to pole; these bands seem to be of firmer texture than the rest of the body, and on them are placed the rows of cilia, which can act either together or separately, so as to give every possible variety of motion to the body. Hence this animal, and others resembling it, are said to belong to the order *Ciliograda*. The Beröe usually swims, by means of them, mouth forwards, through the water, and thus a current of water is driven into the stomach, without any further effort on the part of the animal. But it is provided with other means of obtaining its food, in two long tentacula, which arise from the posterior part of the body, and are furnished



Beröe: *a*, *a*, tentacula; *b*, mouth; *c*, termination of intestine.

with a number of lateral filaments; these can all be withdrawn and folded into two cavities, excavated, as it were, in the substance of the body, and are easily unrolled when required for use.

A very common form of this class in some climates is the *Physalus*, known to sailors as the Portuguese Man-of-War. This is distinguished by its large air-bag, surmounted by a vertical membrane or crest, which usually floats above the surface of the water, and is acted upon by the gentle breeze, in the same manner as the little sail of the Velella. The animal organs placed below are very obscure in their character. No distinct stomach can be perceived; but the tentacula are dilated at their roots into chambers, of which each may perhaps be regarded as a digestive cavity. Some of the tentacula are very long, and hang down in the water to the depth of fifteen or twenty feet when the animal is floating. They possess considerable stinging power, and probably serve to entrap the food upon which the shorter tentacula, with their sucker-like extremities, then affix themselves, for the purpose of taking up nutriment by absorption. These Acalephæ have been termed *hydrostatic*, from the power they possess of rising or falling in water, by increasing or diminishing the bulk of the air-bag; but by what means they effect this change is not known. In some species, comprehended with the *Physalus*, in the order Physograda, several small air-bags exist, instead of a single large one. These are usually fixed to the same stalk, like currants upon their stem, and this rises out of the apparatus of tentacula, &c., of which the animal may be said really to consist.

Physalus.

The Acalephæ inhabit all climates, but the largest forms are to be seen in tropical seas.

CLASS XXII.—POLYPIFERA.

The animal character of the beings composing the class Polypifera was formerly doubted, as that of the Sponges is at present. The structures which they form, known as Corals, Corallines, &c., have often so much of the plant-like aspect, and sometimes also of an apparently woody structure, that, even in recent times, naturalists have been deceived into a belief in their vegetable nature.

Another popular error in regard to this group, is the attributing the formation of coral to *insects*, and the supposition that it is their habitation, constructed under the same circumstances as the comb of Bees, or the pyramids of the Termites. Now, the real fact is, that the masses of *coral*, *madrepore*, &c., as well as the *sea-fans* and other similar structures, with many smaller and more delicate ones, of which some are ranked among the *sea-weeds*, and others commonly known as *corallines*, are the *skeletons* of the animals by which they are produced, and are to be regarded as parts of the living structure, so long as the flesh which clothes or lines them retains its vitality.

If, for example, the stem of the common *red coral* be examined when clothed with its living flesh, its surface is seen to be scattered over with polypes, the structure of each of which bears some resemblance to that of the sea-anemone; but these, so far from being independent of one another, like so many sea-anemones attached to the same rock, are connected by a system of vessels which traverse the flesh, and bring them all into communication. Nevertheless, any one of these would live if detached from the rest, and would gradually produce others, until a new structure is formed, similar to that of which it was a part. Moreover, if a piece of the gelatinous flesh be stripped from *this* will be competent to form both new poly new skeleton.

Such compound beings, then, of which th only form a part (like the leaves or flowers are not improperly termed Polypifera or Po ing Animals. But there are many kinds which have no tendency to this kind of aggreg which are never found but in a solitary state, the *Sea-Anemones*, and the *Hydra* or fr Polypes. And various degrees of intimacy of between the polypes of compound structure traced in different species; some of these will after noticed.

The class may be divided into four orders terised by four distinct types of structure; these we shall find polypes existing almost or independently of one another; and species cl to these, in which they are intimately assoc the distinguishing characters of these orders understood without a knowledge of the structu polypes belonging to each, it will be better to at once to the description of them, the s popular information on the subject being u shall begin with the one generally accep simplest.

Order I.—Hydrophda.

The *Hydra*, or fresh-water Polype, is a minut often found in great abundance, clustering ro tic plants in stagnant pools. It seems to consist only of a kind of bag, constituting its stomach, round the mouth of which is disposed a circle of long arms or *tentacula*, whilst the opposite end is prolonged into a foot, terminated by a kind of sucker, to which the animal attaches itself. The changes of form in this polype are very remarkable. The body has sometimes the shape of a long cylinder, whilst at others it is contracted into a sphere, the arms having shrunk alike into s jections around the mouth. This appearance rally presented when the stomach is rep food.

Hydra.

The *Hydra* is an extremely voracious anim although little able to move from place to secures an abundant supply of food by its la which serve as so many fishing-lines. When tic worm or insect touches one of them, it is by it, and other arms are speedily brought to ance; so that, by the simultaneous contracti whole, the prey is conveyed to the mouth, even enough to make powerful resistance. Not unf it can be seen to move about violently w stomach for some little time; but the power tive secretion speedily begins to act upon it, a parts are dissolved, the hard ones being usual by the mouth. When this solution has been p the fluid which results from it is seen to be d by a kind of circulation through the walls mach and the arms.

Nothing in the history of the Hydra is s able as its power of being multiplied by div of repairing the effects of other rough treat regard to this, there really seems no limit. can the body reproduce the arms, the mouth r tail, and the tail the mouth; but, from a minut the perfect Hydra is reproduced, so that an cut up into forty or fifty pieces, will be con as many separate polypes. Two bodies, al grafted together by the side, the tail, or in way; and monsters with two heads, two tails be easily produced. It was, in fact, on acco tenacity of life and tendency to reproduction

nce of injury, that the name Hydra (after the ous monster of ancient times) was given to this creature when first discovered about a century The power of any one part to perform the func- of the rest, is remarkably shown by the fact, that olype may be turned inside-out; so that what was e the lining of the stomach becomes the external ument, and vice versa, without its comfort being sibly impaired.

e Hydra is not known to subdivide spontaneously, ever, but it propagates itself by a process resem- the budding of plants. A little knob first projects the side of its body, this enlarges, and from the if it are seen to spring a number of small processes, are the arms. In the centre of these an opening ars, constituting the mouth of the young polype, gradually assumes the form of its parent, and to catch prey for itself. Still, however, the of its stomach communicates with that from which at first prolonged; but the passage is gradually wed, and at last obliterated. When quite inde- ent, the young polype detaches itself from the e, and has no further relation with it. Several of buds may spring from the same polype at once, ded it be well supplied with food, and the tempe- be warm; and a second generation may even themselves upon the first, whilst still continuous the parent structure.

e entire substance of the Hydra is soft, and no seems possessed of greater firmness than the rest. me other species, how- we find a tendency to consolidation of the ex- into a kind of horny or sheath; and when ber of polypes are ated together, a com- l structure is thus pro- . In these compound tures the cells are ected by stems and hes, in the same man- e the buds of a plant; through the base of cell there is a canal

Portion of Sertularia: a, a, polype-cells with polypes; b, b, coastal vesicles.

by an extension of the lining membrane of the e, and uniting with the channels which pass gh the whole structure. Thus, all the polypes are ght into connexion with each other, and with the ral mass or polypary.

ese polyparies, formed by the association of hydra- polypes, are among the most graceful and elegant the structures with which this class presents us. are of minute size when compared with the mas- productions of other tribes; and the uniform ace of stony deposit gives them a degree of flexi- which adds much to their gracefulness. There few shores on which some forms of them may not cked up. They are commonly mistaken for sea- s.

se polypes, being enclosed in cells, do not share in function of reproduction, for which a special appa- s is evolved. A set of horny vesicles (*b*, *b*,), usually h larger than the polype-cells, are developed at in- als from particular parts of the stem and branches; it is in these that the reproductive bodies or gem- s are formed. Each vesicle is provided with a lid, h falls off when the gemmules are mature and y to swim forth; and the vesicle itself afterwards vals and drops away, like the seed-vessel of a plant has shed its seeds. The whole of this process very h resembles the fructification of mosses, in the mode hich it is carried into effect.

he forms of Polypifera allied in structure to the ra, compose an order which may be termed that of oma, or *Hydriform* Polypes. This order is pretty ersely distributed over the globe; not abounding e in tropical than in temperate regions. Scarcely fossil remains of it are to be found.

Order II.—Helianthoida.

A common form of polype, apparently so different from the Hydra that the relationship between them would not have been suspected by an unlearned observer, is the *Actinia* or Sea-Anemone. There are probably no shores over the whole globe, except the very coldest, on which some species of this interesting creature are not to be found. The mouth is in the centre of the upper surface, and is surrounded by tentacula; and these are numerous and arranged in several rows. The under side forms a large sucker or disc; by this a very firm hold is taken of the rock or other surface to which the animal adheres. The stomach does not occupy the whole cavity of the body, but only the central portion; and the space between its wall and the outer integument is divided, by vertical membranous partitions passing directly from one to the other, into a number of radiating chambers, in which the germs of young *Actinia* are produced, and sometimes nearly matured. The tentacula are hollow, and their cavity is continuous with that of these chambers; at the extremity of each is a small aperture, through which water is occasionally taken in, and then ejected with considerable force. This process seems to be of the nature of the action of respiration in higher animals.

Actinia seen from above.

Section of Actinia: *a*, cavity of stomach; *b*, surrounding chambers.

The tentacula of the Sea-Anemone can be contracted in the same manner as those of the hydra, and they are furnished with a sort of sucker at their extremities, by which they can draw towards the mouth any substance which comes in contact with them. Although each seems weak in itself, the combined action of many is sufficiently effectual for maintaining an ample supply of food. These animals are extremely voracious. Not being able to move from place to place in search of particular kinds of nutriment, they are adapted to digest almost any which comes within their reach. Shell-fish and small Crustacea appear to be their usual diet. These are swallowed alive, in spite of their struggles, but are soon destroyed by the powerful solvent action of the juices of the stomach. The hard portions are ejected from the mouth; and, in getting rid of them from its stomach, the Actinia often inverts the lining of the latter through its entrance, so as almost to turn its body inside out.

The powers enjoyed by the Actinia of reproducing different parts which have been removed, and of multiplication by the division of its body, are nearly as great as those already described in the hydra. It may be divided either vertically or transversely, and each part will in time supply what was deficient, and become an entire animal. This reproduction has taken place in some instances from small fragments, but it does not appear that the same number can be reproduced by the subdivision of one, as in the hydra. We do not find here the same process of multiplication by buds, as in the hydra; but distinct germs, or *ova*, are formed in the radiating chambers which surround the stomach (hence called *ovarial* chambers), and from these, as from the eggs of higher animals, new beings like the parent are produced. The development of them may take place whilst yet within the body of the parent; and thus, as the young ones pass out from the mouth, it appears to cast them up from its stomach.

The sea-anemone is not the only solitary polype possessing the kind of structure which has just been de-

scribed. Several other species exist, in which the same type is presented with various modifications.

There are some among them which form a stony deposit in the substance of their base, and in the membranous partitions between the radiating chambers. Of these one small species inhabits the British seas; it belongs to the genus *Caryophyllia*. A very beautiful coralline formation of this description is that produced by the *Fungia*, an animal allied to the sea-anemone, and inhabiting only tropical seas. It consists of a thick round plate, sometimes several inches in diameter, from one surface of which arise thin vertical plates, radiating very regularly from the centre to the circumference. This is, in fact, a single cell of a large solitary polype, and from it the structure of other coralline masses will be understood.

The cells of such solitary polypes are not always round, but are sometimes very much prolonged in one direction, so that the depression in the centre, marking the place of the mouth, towards which all the radiating plates are directed, becomes a long groove. These stony masses contain a considerable quantity of animal matter, by which the particles of carbonate of lime are glued together; and when a sufficiently fresh specimen of a stony coral is submitted to the action of an acid which dissolves these, the animal substance will retain its form.

Mass of Astræa Viridis:
a, *a*, expanded polypes; *b*, *b*, polypes withdrawn into their cells; *c*, stony mass uncovered by flesh.

The number of stony corals formed by the compound Polypifera is very great; and, of the more massive kinds, a large proportion belongs to this order. Those which are to be ranked as the skeletons of animals allied in structure to the sea-anemone, are distinguished by a character very easily recognised. In each cell, however minute it may be, the arrangement of radiating plates, described in the *Fungia*, is seen; and from the presence of these thin plates, or *lamellæ*, the whole of this group of corals and madrepores have been designated as *lamelliform*. A lamelliform coral is, then, always formed by a polype similar to the sea-anemone (or *actiniform*); and thus, by attending to the mode in which the growth of the coral depends upon the structure of the animal, we obtain a valuable character, on which we can always rely.

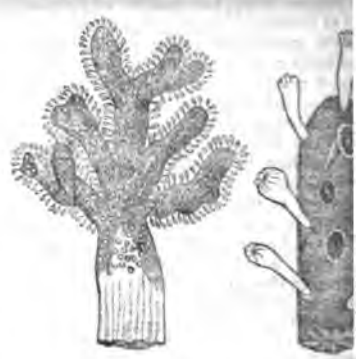
The individual polypes belonging to such structures are connected by a gelatinous flesh enveloping the whole, which seems to answer to the membranous pith lining the stems of the compound Hydroida. It is by this flesh, rather than by the polypes themselves, that much of the stony mass is deposited, as may be seen by examining many species in which the intervals between the cells are considerable. The variety of aspect which these masses present is very great, but there is little difference, so far as is known, in the structure and habits of the individual polypes, which form part of the beings in their living state.

None but *stony* corals are formed by Polypifera of this order; but there are many of that description which do not belong to it, of which we shall speak. However, it is to this order that t part of those species belong which are en erecting the massive structures known at pre the names of coral reefs and islands, as w which appear to have existed in still great in former epochs of the earth's history, as given origin to the greater part of the lime which constitute so large a proportion of known to us. This order may be denomina *Actiniform* Polypes, from the general resem the animals composing it to the sea-anemon *anthoida*, from their similarity in aspect, when to the sun-flower.

Order III.—Asteroida.

The next order of Polypifera is one whic nearly to the form of the Sponge. In the groups we have been last considering, the po an important part of the general structure, a instances each may be regarded as existing itself alone, even where many are united t necting fleshy matter. But in the group treated of, the polypes seem quite subordina general mass seems to have (as in the spo more of the character of a single individual structures we observe, too, that the hard ba ton is seldom so distinct from the living tiss lamelliform corals, the two often passing other by almost insensible gradations. Th the skeleton varies considerably in the differ Sometimes it is of a spongy character, as i *onia*; sometimes of a stiff horny texture, as *gonia*, or Sea-Fan; and sometimes of a ston as in the Red Coral.

The *Alcyonia* are found abundantly on of the British shores, and are known to fi



Alcyonium:
A, portion enlarged, showing the polyp

the names of *dead-man's hand*, *sea-finger* &c., from their flabby texture, and the pec they present. Their structure is spongy, bu usually a more distinct envelope than the tr and this has sometimes a leathery charac interior is traversed by a series of canals, w and inosculate with each other; and, on c the mass, it is observed that nearly the wh composed of a network of these passages, s the animal fibrous tissue, which is sometime into a fabric of considerable firmness. The have no direct external opening, however terminate in prominences of the spongy which the polypes protrude.

The polypes themselves have some res the sea-anemone, but they are usually sm and of more delicate structure. There ar some important differences, upon which th of the order is founded. The tentacula, inst numerous, and arranged in several rows, ar

aber, and form one circle. They are broad, and leaf-like, instead of being round and slender. outh is situated in the midst of them, and leads stomach, which occupies the centre of the body; d the stomach are the *ovarial chambers*, separated iating partitions, but only eight in number. The ch opens into the canal upon the end of which the is placed, and all the fluid which enters the appears to be taken in through these mouths. varial chambers also communicate with the canal ch, indeed they may be said to be a continuation for the partitions between them are prolonged wards into the canal, forming plaits or folds of its membrane, in which the ova or germs are deve-; so that these are produced from the general rather than from the polype, and the whole struc-may be regarded as a higher kind of Sponge.

polypes are capable of being drawn entirely the protuberances on the surface of the *Alcyonia*, ven these projections become flattened when the ds are in a state of great contraction. In this con-they are often left by the tide, and if then placed lass of clear water, their gradual expansion may tched. The protuberances from the surface first themselves, and the polypes, one by one, appear eir summits, and slowly expand their tentacula, the whole surface appears covered with delicate oms. The entire mass then not unfrequently swells ice or thrice its original size. If any one of the es is irritated, it shrinks into its hiding-place, but near it are not affected. If the irritation of the be prolonged, however, those in the neighbourhood ually show themselves influenced by it, and draw selves in; and in this manner the whole mass may timately affected. The same effects, however, may oduced by irritating a portion of the spongy sub-e intermediate between the polypes. From this evident, that sensibility to impressions is not con-to the polypes alone, but that the whole mass must garded as possessed of animal properties.

e *Alcyonia* grow in the same circumstances with ges, and their correspondence is further shown by existence of crystals of silex in their tissue, which not found in other polype-structures, the earthy er in these being entirely calcareous. The diffe-species of the Alcyonia, like those of the Sponges, be distinguished by the form of the spicula pre-ed in the skeleton.

other forms of this order we find the skeleton, rm support, in a more concentrated form. Thus e *Gorgonia*, a beautiful framework of horny mat-consisting of a stem and a minute network of ches, occupies the centre of the structure; and this othed with a soft flesh, through which the channels that connect the polypes together. This flesh is red with a firm skin, in which a great amount of hy crystals is deposited, so as to form a crust; and is are the hollows or cells by which the polypes are ected. In the dead structures, with which we are iliar under the name of *sea-fans*, the dark horny ible stem is seen to be covered in many parts with a tle crust, often brightly coloured, which can be ed off it and crumbled to powder. Between the , in the living state, the fleshy coat existed; the r part of it being in contact with the exterior of the y stem, which was then soft and scarcely distinct n it, whilst the exterior part was consolidated by earthy matter into the firm integument.

n the *Isis*, we find less stony matter on the outside of the flesh, but a deposition of it at intervals in the stem, which thus obtains a jointed character, being flexible at the points at which the horny matter has not been consolidated. And in the *Red Coral*, the entire stem is converted into a very firm stony axis, which presents no indication of polype-cells, these being excavated only in the flesh that clothes it. The *Pennatula*, or Sea-Pen, is an interesting species belonging to the same group, and in some respects resembling the Red Coral; it has a stony axis, but this is flexible at the extremities; and it is not attached by a solid basis, but is carried about by the mercy of the waves. From the central axis, which is nearly straight, a regular series of lateral branches passes off on each side, like the barbs of a feather; and on these the polypes are situated. By the simultaneous movements of their tentacula, the animal (if it is to be called *one*) seems to have some power of directing its course, if not of propelling itself through the ocean. A small species, which is luminous at night, inhabits the British seas.

Single Polype of Pennatula.

Pennatula.

There is one species in this order which differs from all the rest in the consolidation of the exterior rather than of the interior tissue; so that a stony *tube* is formed instead of a central stem. This is the *Tubipora Musica*, of which the skeleton is known as Organ-pipe Coral. The polypes are not here connected by any system of vessels or uniting flesh; each lives for itself alone, but a number (probably all produced from the same stock, and by offsets from each other) unite for mutual support in one structure. Each polype has a cylindrical form, and its exterior membrane is progressively consolidated into a stony tube, which is thus gradually increasing in length by new deposits at its upper end. At certain intervals the soft membrane (which is always projecting beyond the mouth of the tube) is flattened down into a sort of collar, which is consolidated likewise; and the collars of the neighbouring tubes coming in contact with one another, form a sort of floor or shelf, which greatly strengthens the mass. After this collar is formed, the tube is continued as before for another period, when a similar floor is again produced by the simultaneous action of the numerous polypes composing this beautiful structure.

To this order the term of *Alcyonian* Polypifera (from the name of one of its principal groups), may be conveniently applied; it is also known by the designation of Asteroida, from the star-shaped form presented by the tentacula when expanded. Its most luxuriant kinds are natives of tropical seas; thus the *Alcyonium poculum*, or Neptune's cup, which abounds in the neighbourhood of Singapore, is one of the most bulky species at present existing. But the smaller tribes abound in our own seas. No massive stony polyparies are formed by the animals of this order.

Order IV.—Ascidioida.

The last order of Polypifera far surpasses all the rest in the complexity of its organisation; although so little distinguished from them in external form, that a cursory examination would not reveal the points of difference. In fact, many of the species belonging to it have been associated with the *Hydraform* Polypes, by naturalists of eminence; and it is only by means of a high and clear magnifying power that their true structure is capable of being ascertained. The stony character of the polyparies formed by others, has led them to be grouped with the *Actiniform* Polypes; and it is only within a very recent period that opportunities have been afforded for that examination of their living condition, upon which alone reliance can be placed.

The polypes of this order seem more independent of one another than they are in the associated groups of the others; but they are not known to exist in an absolutely isolated condition. A species lately discovered on the

land, at a distance of usually more than a leagues from the coast. This is above a thousand g; and for several hundred miles has no break ugh to give passage to a ship. It is scarcely ble that a submarine ridge of hill should exist, nd miles in length, and approaching every where o hundred feet of the same elevation; for such s nowhere seen on the dry land. But it is easy us far this remarkable structure, if we suppose ridge was formerly more or less elevated above hese; and that its different parts gradually ncrusted and capped with coral as they were ed, after which the growth would continue e same parts, until the whole, being thus d and covered, became the continuous mass now witnessed. That such depressions *are* ace in some islands of the Pacific, is a fact estab-d, not only by the traditions of the natives, but vations made since they have been visited by ns.

are many instances in which the coral struc-comparatively recent origin have undergone a rphosis, which causes them to lose in some heir original aspect. Large masses, when long to the air, become changed into a solid, often at crystalline, rock, in which the traces of structure are very indistinct, and with which *stain* or *secondary limestone* closely corresponds. bserved in the Bermudas. Moreover, the coral n becomes agglutinated, by the percolation of rough it, into a very hard stone; it is in such hat the human skeleton, found on the shore at upe, and now placed in the British Museum, is d. This stone, when minutely examined, is onsist of a number of rounded grains, cemented, e, together; and it closely resembles the rock o the geologist as *oolite*. Further, where shallow ists around coral islands, the bottom is found ered with a layer of white mud, which is formed decay of the animal matter that held together icles of carbonate of lime in the stony corals, se are consequently set at liberty in a finely-state, and fall to the bottom in a form which, if ld constitute chalk. Thus we may trace, very y, the mode in which the three principal kinds ome rocks may have taken their origin in coral ns.

the mountain limestone, as it is termed—a rock ndant in Britain, extending over large areas the coal-fields, and sometimes exhibiting a thick-nearly 3000 feet—is in some parts evidently d of accumulations of shells, stems of encri-e. But in many others, the remains of corals distinct; and these are so blended with the ring rock as to make it appear probable that r also was once in the state of coral, but was y changed by the process just described. Par-e collections of other animal remains are just we should expect to find on the margin of a f or island existing at that epoch; and a simi-ess of fossilisation is taking place in the shores existing at the present time; the imbedded animals only being different. The great thick-he beds of this rock may be very well accounted he same manner as the depth of the coralline f recent formation.

are observed, in rocks of more recent forma-pearances which still more clearly indicate that o were originally formed by coral-polypes. re often found only within narrow limits, as if been reefs or islands of small size. Thus we one called coral-rag in Oxfordshire; and very coral beds in the crag of the eastern coast of . It is interesting to remark, that the remains which are found in the older limestones, all nd with those at present abounding near the and exhibit the *lamelliform* character; whilst gradually replaced in the newer strata by spe-e allied to those at present existing, to some-

rate climates. This is one of the many facts which tend to prove that this part of the earth had at some former period a much higher temperature than at present.

We see, then, that vast as are the works of the existing species of this class, they are probably far surpassed by the accumulations of former ages, which constitute, in some form or other, a large proportion of the solid rocks of our terrestrial surface. And thus we see the exemplification of a principle which has frequently come under our notice—that in the economy of Nature nothing is insignificant; and that the most gigantic effects may be produced by the multiplication even of the humblest among the living inhabitants of the globe.

CLASS XXIII.—PORIFERA.

Of all the beings usually known under the designation *Zoophytes*, the *Sponges* and their allies, constituting the class Porifera, appear to have the best claim to the title; since they present so complete an admixture of the characters of plants and animals, that it is difficult to say to which division of the organised world they properly belong. Like plants, they are fixed to one spot during the whole of their lives, subsequently, at least, to their first development; they seem to possess no sensibility, for they can be torn or wounded in any way without showing by their movements any indication of being affected by the injury; and they do not appear to have that power of executing voluntary motions which must be regarded as the distinguishing characteristic of animals. On the other hand, they present a structure which is not analogous to any thing found in plants, but is similar to that of beings undoubtedly belonging to the animal kingdom; with these beings they are connected by intermediate forms, presenting a regular gradation of increasing complexity of structure and variety of function; and there are certain movements, both in the adult and in the undeveloped Sponge, which are more analogous to those seen in higher animals than to any observed in plants. On the whole, however, the evidence for the animal character of the *Sponges* seems to preponderate; and they will be accordingly considered here. Still there is no doubt that, if they are included in the Animal Kingdom at all, the lowest place in the scale should be assigned to them.

The common *Sponge* is a sufficiently characteristic form of the class, to serve as the foundation of a general

Section of Living Sponge.

account of the structure which prevails in it. On looking at its exterior, we observe that it is covered by a number of closely set and minute orifices; and that larger openings are disposed at intervals among these. The former are termed *pores*, the latter *vents*. On cutting into the substance of the sponge, it is seen to consist of a sort of network of filaments, interlacing together in such a manner as to leave large channels and spaces of various forms, which communicate with each other. The large channels terminate in the vents; and, [illegible]ging any one of them into the substance of the [illegible], it is seen to divide and send off ramifying [illegible]es, which at last lose themselves in the spongy [illegible]k that lies around them; and this communi[illegible] with the pores on the external surface.

The interlacing fibres, of which the walls [illegible] canals, and the spongy tissue between them, are composed, entirely consist (in the common sponge) of a sort of horny animal matter, as is shown by [illegible] a small portion of them. But in other species [illegible] *spicula*, or needle-like crystals, of silex or [illegible] of lime, disposed amongst these, giving to [illegible] ture much greater firmness, but depriving [illegible] less completely, of that elasticity which is [illegible] the common sponge.

The substance known as sponge is, however, [illegible] skeleton of the being; when alive, this fibrous [illegible] is clothed, within and without, by a thin [illegible] substance, very like the white of an egg. This [illegible] the passages, and covers the exterior; but [illegible] away when the sponge is removed from the [illegible] this the peculiar vital endowments of the [illegible] to reside. These are manifested, not only [illegible] but regular growth, but by a curious circulation [illegible] constantly taking place within the mass. When [illegible] is examined in its living state, beneath the surface [illegible] stant current is seen to issue from the vents [illegible] made evident by the disturbance of the water [illegible] the movement of particles floating in it. It [illegible] be ascertained that a constant flow of water is [illegible] inwards through the pores; for small solid [illegible] upon their edges are occasionally seen to [illegible] No intermission can be detected, during the [illegible] sponge, in these currents, which evidently have [illegible] object to convey the nutritive matter contained [illegible] water into the interior of the mass, and also [illegible] off the particles which are to be excreted. [illegible] films detached from the living tissue are seen [illegible] out from the vents along with the fluid specially [illegible] them.

The relative position of the *pores* and *vents* [illegible] much in the different kinds of sponge. Sometimes [illegible] the former are on one side, and the latter on the [illegible] Not unfrequently the vents are placed on the [illegible] of little conical prominences, which look like [illegible] a volcano; and the stream issuing from them [illegible] seen under a microscope, may be likened to a [illegible] eruption. Sometimes the sponge assumes the [illegible] a hollow cylinder, which hangs at one extremity [illegible] rock; the pores are all upon the exterior [illegible] whilst the vents open into the interior cavity, [illegible] united stream rushes out with considerable [illegible] from the lower end of the cylinder.

Sponges may be multiplied, like plants, by [illegible] division, each portion becoming a new individual [illegible] it does not appear that this is their natural [illegible] increase. They propagate by detaching little [illegible] gelatinous bodies, termed *gemmules*, from the [illegible] tissue; which in time develop the original form [illegible] parent. These are produced in the network of [illegible] the large canals, into which they find their [illegible] when mature, they pass out of the vents in the [illegible] rent which sweeps through them, and by which [illegible] are conveyed to a distance. In these gemmules [illegible] liar motion, like that of animalcules, may be [illegible] some time; they swim hither and thither; at [illegible] fix themselves, and begin to deposit the horny [illegible] particles which are to form their skeleton; [illegible] system of canals gradually shows itself in the [illegible] stance. When once they have fixed themselves [illegible] seem to lose all power of further movement, and [illegible] during the rest of their lives attached to the [illegible]

Some kinds of sponges are found on almost all [illegible] and some frequent deep water, whence they [illegible] be obtained by dredging. It is in this manner [illegible] common sponge is procured from the Mediterranean, the Grecian archipelago, and the other localities [illegible] quents. Sponges are not confined to the sea, [illegible] for there is a species which inhabits fresh water [illegible]

With the notice of this group we appropriately [illegible] the subject of Zoology.

rmits their free and unhampered play. The
sion is seen in the construction of the ten-
fingers. There are two principal muscles
the joints of the fingers, and two sets of
ich are inserted, the one into the middle
e finger, the other into the third row of
the extremities of the finger. In order
their free action, and to make them lie
convenient manner, there is a loop or slit
rter tendon, by which the other passes
its insertion in the point of the finger. By
this means, the longest and strongest muscle moves the extremities of the finger, where the greatest power is wanted, without impeding the action of the other. The muscles which move the lower extremities are thicker and more powerful than those of the arms. Several large muscles, acting in opposition to each other, are situated around the thigh-joints, and move them. They are fixed, one end to the trunk of the body, some pretty far up, especially two, which are spread upon the front of the abdomen or belly, on each side of the spine, while the other ends are attached to the thigh-bone. Several thick muscles, also, are situated at the back of the trunk. Two large muscles compose the calf of the leg, and join to form the tendon of Achilles, which is fixed to the heel-bone; these muscles act powerfully in bending the ankle and in supporting the body in walking. The foot and toes are moved by several long slender muscles, situated in the leg, which have tendons attached to them, and terminating on the toes, exactly like those of the hand and fingers. The pelvis and lower limbs of man differ greatly from those of all other animals in their superior proportional strength, and in the number and fullness of the muscles. This was necessary, as man has been evidently intended by nature for the erect position. In the monkey tribe, whose general form approaches nearest to that of man, the narrowness of the pelvis or hip-bones, and the smallness of the muscles of the lower extremities, clearly show that they were not destined by nature for the erect attitude; in fact, all animals of this class are furnished with four *hands* or *paws*, the hinder pair exactly resembling those in front. When they attempt to walk on the hind extremities, they cannot put the sole to the ground, but press on it edgeways. By the nice balancing of the muscles, and the great force which they exert, man is enabled to stand erect, and to maintain a firm position, or move forward at pleasure, notwithstanding that the body diverges from the perpendicular line of the centre of gravity. The head is also balanced upon the neck by means of strong muscles, whose constant though unobserved exertion is necessary to maintain it in its position; for in young children, when the muscles are as yet weak, and in persons asleep, the head has an inclination to droop, and in the dead body it falls down on the shoulder or breast. The muscles of the neck, therefore, may be said to exercise a power in some degree involuntary, or not under the command of the will, as the majority of the muscles of the body are. But there are other muscles still more distinctly removed from under the guidance of the will. The heart is nothing else than a hollow muscle, which contracts and expands without the consciousness of the being; and, in like manner, the muscles which perform the act of respiration are not moved by the will. This division of the muscles into two classes, shows as perfectly as any thing could do, the care with which our frame is constructed. Had those muscles on which respiration and the action of the heart depend, been placed under the control of the being, their functions would have been liable to be impeded, at every turn, by circumstances. Now, these organs cannot cease to act for the most trifling period of time, without fatal consequences. The arrangement, therefore, which renders their operation involuntary, is one to be admired as essential to life and comfort.

THE BLOOD—BLOOD-VESSELS.

The Blood.—The blood is the medium by which all the solid and fluid parts of the body are supplied with nourishment. In its composition, therefore, will be found the majority of the substances of which the body is composed. The blood consists of a solid coagulable matter, called *fibrin;* of a series of *red globules* which form the colouring matter; and of *serum*, or whey-like matter, which gives the whole the necessary fluidity. From the heart, the centre of the circulation, the blood is conveyed through the body by vessels called *arteries*, and is brought back to the same part by *veins*. The
pose of thus making the circuit of the whole

whole. After traversing the body, it returns to the heart, deprived of its nutritious properties, and changed in colour from a bright to a dark red. Here the second circulation, which is through the lungs, commences. The blood is poured from the right side of the heart, which has divisions for the purpose, into large vessels which carry it to the lungs, and, spreading out into countless branches, penetrates and permeates their whole substance. Collected again by other vessels of equal number and extent, it is conducted by them to the left side of the heart, to be propelled anew through the frame, restored to its bright red hue, and repossessed of all its vivifying qualities. Both these changes are effected in the lungs. The chyle, which may be called the essence of our food in a liquid state, is conveyed from the stomach through the chest by a duct, which empties itself into one of the veins, immediately before the blood is transmitted through the lungs. It is in these organs that the chyle is thoroughly mixed up with the circulation ; and it should be remembered, that this chyle is the only benefit, the only real food, extracted from all the substances received into the stomach, the remainder being entirely useless and excrementitious. From the chyle comes the material of the bones, of the fleshy or muscular parts, of the brain and nervous cords, of the hair, nails, enamel of the teeth, and, in short, of every different structure of the system. The average quantity of blood contained in an ordinary-sized person, is calculated at about 30 lbs. weight. The coloured globules of blood do not enter into the smallest vessels of the body, but only the thinner part of it, which has no colour ; thus, in the eye, there are numerous blood-vessels, but these are so minute as not to admit the red parts of the blood ; and this is a necessary provision of nature, in order that these organs may retain their pure transparency for the purpose of vision. In inflammation of the eyes, when these vessels are much enlarged, the red globules sometimes enter, and the eyes are then said to be bloodshot. What is called the pulse, is the flow of the blood thro the arteries, which is caused partly by the im- ... the heart's contractions or beatings, and partly

The Brain.

nerves are small whitish-looking cords, which proceed from the brain and spinal marrow, and spread out in innumerable branches to every part of the body. A large branch of a nerve generally accompanies every large artery, and every important part of the body has a branch of a nerve sent off to it. The nerves for supplying the organs of smell (1), of seeing (2), of hearing (3), together with the great sympathetic nerves, which give branches to the heart, lungs, stomach, and other important viscera, proceed directly from the brain. The nerves of motion and sensation sent to the various parts of the trunk and extremities, take their origin, with a few exceptions, from the spinal cord. Two sets of nervous branches proceed from the cord on each side, corresponding nearly to the junction of every vertebral bone; and it is found that a branch of these nerves imparts motion, and the other sensation or feeling. The brain has a covering of three thin membranes; the outward one strong and thick, the inner extremely thin and delicate. The nerves, which are soft and pulpy inside, have also a thin external covering which protects them. The nervous branches are never seen or felt in the living body, and what are vulgarly called nerves, are the tendons of the muscles, the erroneous title being given chiefly to those about the wrists, fingers, and ankle-joints. Their great numbers and minute divisions are manifest, however, because we cannot prick any part of the body with the sharp point of a needle, without wounding some of them, and thereby causing the sensation of pain. When the nerves are injured in their powers by disease, the sense of feeling in the part is entirely lost. The brain in the lower animals is not generally nearly so large, in proportion to their bulk, as in man; and the cerebrum, or upper brain, is often smaller in them than the cerebellum, or lower brain. In many classes of the inferior animals there is no distinct brain, but only nerves running along their bodies, and joining into knots or ganglions. The nervous system of insects and worms is of this description. In the polypus, and some other similar animals, a distinct nervous system can scarcely be traced.

It may be proper here to make some observations on the functions of the brain, considered abstractly from its anatomy. Man surpasses all other animals in the height and proportions of the forehead, and in the comparative mass of brain in the upper part of the skull. In the human head the lower parts of the face bear a smaller proportion to the forehead than in the brutes. The face is placed in nearly a perpendicular line with the forehead, instead of projecting outwards into a snout, as in the lower animals. The brute face is merely suited for the purpose of animal wants and for defence; the jaws are long and narrow, supplied with thick, strong muscles, and short teeth; there is not the elevated nose, which in man forms a distinguishing feature—the arched eyebrows—the exquisitely formed lips, and the rounded chin; above all, there is not that play of varied expression, that air of intelligence, and that indescribable emanation of a rational mind, that ray of divinity, at the appearance of which the most wild and ferocious of the brute creation are awed and subdued. But, besides, the Creator seems to have allotted characteristic external signs to express the passions of the mind, that in social life man might not easily impose on his fellow-man; for the various muscles of the face express the several passions of the mind so faithfully, that they may be even represented in painting. This is said to be the natural expression, and would appear to be understood even by animals; for a dog, on looking to the countenance of his master, easily recognises the mute expressions either of commendation or dissatisfaction. From the action of these muscles being so often repeated,

physiognomy arises; the action of the prevailing muscles fixes an enduring expression on the features; and thus traces of frequent anger often remain in the countenance after the passion itself is gone off. With the power of speech and reason, man has also the means of expressing his feelings and passions by laughter and weeping, manifestations which are not found in the lower animals. Weeping proceeds from a deep emotion of the mind, and seems an effort of nature to relieve the system of grief. It usually begins with deep inspirations of the lungs, after which follow short alternate inspirations and expirations, and it is finished with a deep long-drawn expiration, which is immediately followed by an inspiration. When moderate, it certainly relieves the distress arising from grief. Laughter has its rise from some ludicrous ideas impressed upon the mind, and would seem to arise directly from a sort of titillation conveyed to the branches of certain internal nerves, probably those of the diaphragm; immediately to this succeeds a number of imperfect inspirations and expirations, which seem to be checked by the contraction of the glottis in the throat or larynx. Laughter in a moderate degree may be conducive to health, as it gives impulse to, and ultimately promotes, the circulation; carried to excess, however, it may prove dangerous, from accumulating too much blood in the lungs. Sneezing consists of one deep inspiration, succeeded by a powerful single expiration, and seems to consist of a convulsive effort of the muscles of breathing to throw off some cause of irritation in the sensitive membrane of the nostrils. The common hiccup is a spasmodic action of the muscles of the stomach, caused by something irritating the stomach itself. Some of the causes by which our mental happiness is either increased or diminished, proceed entirely from the bodily sensations. Any gentle stimulus applied to a nerve seems to cause a feeling of pleasure; strong stimuli, or any causes disturbing seriously the natural condition, produce pain. Itching is akin to pleasure, and in both cases the flow of blood is increased into the part in which either pleasure or titillation is perceived; but when farther increased, it degenerates into pain, or excessive sensations in the nerves. Anger violently excites the motion of the spirits, increases the motion of the heart, the frequency of the pulse, and the strength of the muscles; forces the blood into the extreme vessels; and even sometimes bursts the smaller vessels themselves: passion also increases the secretion of bile. Grief weakens the strength of the nerves and action of the heart, retards the pulse, destroys the appetite, and frequently produces paleness, looseness of the bowels, indigestion, and those slow or lingering diseases that take their rise from an interruption of the secreting glands, and a disease of their structure. Fear diminishes the force of the heart, weakens the muscular motions, relaxes the whole system, and, if long continued, causes a general sinking of the body. Excessive terror often increases for the moment the muscular strength, even to convulsions; excites the pulse, interrupts the course of the blood, and in not a few instances has produced sudden death. Love, hope, and joy, promote all the salutary actions of the body, gently quicken the pulse, promote circulation, increase the appetite, and aid the cure of diseases. Excessive and sudden transports of joy, however, often prove fatal, by increasing the motion of the blood, and exciting a fit of apoplexy. Shame, in a peculiar manner, retains the blood in the face, as if the veins were obstructed; when felt in an extreme degree, it has also been known to prove the cause of sudden death.

THE LUNGS OR BREATHING APPARATUS.

In the highest part of the cavity of the chest, on each side of the breast-bone, the lungs are situated. A membrane passing from the breast-bone to the back, divides them into two portions, the right lung and the left lung. The right lung consists of three sections called *lobes*, the upper, middle, and lower; the left lung, rendered smaller in bulk by the presence of the heart in the same cavity, has only an upper and a lower lobe. The lungs have a dark bluish appearance, a fa ample of which is afforded in the *lights* of a part generally appended to the heart and Inside they are composed of an immense n cells, which alternately inflate or collapse as are filled and emptied of air. When an ins made, and the lungs are filled with air, thes come expanded; and the blood sent from the of the heart, and spread over the cells, is expose an extremely thin membrane to the air. An change, as formerly alluded to, here takes pla blood: from being of a dark purple colour, diately changes to a bright scarlet, having ab taken up all the oxygen, or vital part of the parted with a corresponding volume of carb gas or fixed air, which it had acquired in through the vessels of the body. So essent matter imparted by the air to the blood for animal existence, that the breathing cannot pended even for a very short period without ing life. It is probable, too, that the heat of is generated, and constantly kept up, in a other, by means of this process of breathing change which the blood undergoes. We know that the evolution of carbonic acid cannot go nary chemical processes, without an accompa charge of heat; and hence it is presumed tha warmth, derived by the body from the bloo in this way produced. The lungs, like ev internal organ, are covered with a thin t membrane called the *pleura*: this membran as the substance of the lungs themselves, is inflammation; and hence the name of the dis pleurisy. The trachea or windpipe, the co tion between the mouth and lungs, is a bo having a series of cartilaginous rings pass it, to prevent the possibility of its being c either by external means, or from the food of swallowing, and, in consequence, the brea structed. It takes its rise from the botto mouth, and passes down in front of the neck, strong cartilage may be seen and felt. At part it divides into two parts, like the prongs one going to join the right section of the lungs, the left. Lungs for breathing air are only fo higher classes of animals. Fishes are furni gills, those comb-like substances which he wit on each side of the head; over them a stream is constantly sent by inhaling it at the m similar manner to breathing. The air, which present in considerable quantities in water absorbed by the blood-vessels while ramifying gills, and all the purposes of breathing are In insects there are no lungs, nor do they h the mouth, but along the sides of their bodies, of numerous holes with small tubes or spira ing to a longer middle tube, by which the and mixes with their fluids. When we dese in the animal scale, even this substitute for ceases, and probably the vital air is absorbed animals by simple pores or openings in the sk

THE TEETH.—DIGESTING APPARATUS.

The first process performed in connexion supply of nourishment to the body is that of ing the food, and this is the office of the teeth.

The Teeth.—These are placed in the upper jaw, to which they are attached by roots, w into the porous sockets of the jaw, somewh same manner as a nail is fixed in a piece though they are retained in place chiefly by parts around. The teeth are composed of bon covered externally with a thin coat of an e hard substance, called enamel. The teeth are with nerves and blood-vessels, and have thus vi the rest of the body, although possessing it perfect degree than most other parts of the Hence they are very liable to disease and de decaying teeth a blackish spot is first perce

sed, the valve again springs open, and admits of
thing. To show how accurately and precisely
rt of the human machine performs its duties, a

ing a sufficiency of nutritious aliment. The

food being received into the mouth, is broken down and masticated by the teeth. It is here also reduced into a soft pulp by the saliva, which flows into the mouth by the salivary glands; and thus being sufficiently broken down and softened, it passes into the stomach. The stomach has numerous glands situated on its inner coat or surface, which secrete a peculiar fluid called the gastric juice, which is clear and colourless, with little taste, or smell, or sensible qualities. On this fluid depends the important office of digestion. It has the power of coagulating substances in the stomach, of preventing the contents of the stomach from passing into a state of fermentation or putrefaction, and of dissolving the whole into one homogeneous mass. When the stomach is first filled with food, it appears to remain there for a short period without undergoing any change; gradually, however, successive portions of the food, as they come into contact with the gastric fluid, are dissolved; till at length, in a shorter or longer period, the whole is collected into a thin greyish paste, called chyme. In the upper or left division of the stomach, it would appear, from some recent observations, that the food is freed from its superabundant moisture, which drains off by some undiscovered means to the blood-vessels, and from thence to the kidneys. The chyme then, as it is gradually formed, moves to the other extremity of the stomach, called the pyloric, where it passes out to enter the intestinal canal. It would appear, also, that the pylorus, or lower mouth of the stomach, has a sensitive power, whereby it freely permits the digested chyme to pass out, but refuses exit to the undigested matter. The chyme having passed into the first part of the intestines, or duodenum, is then mixed with the bile from the gall-bladder, and with the pancreatic juice. Both these substances, especially the bile, seem essential for the conversion of the chyme into proper alimentary matter, but their peculiar action has not yet been satisfactorily explained. That the liver and bile ducts are of the utmost importance, however, cannot be doubted, from their magnitude, and the care with which they are supplied with numerous vessels, and from their being universally present in a great proportion of animals. The chyme having passed through the duodenum, and having been mixed with the bile and pancreatic juice, now changes its appearance and properties, and becomes the chyle, or nutritious matter destined to supply the various parts of the system with nourishment. The digested mass is passed gradually along the course of the small intestines, urged forward by what is called their *peristaltic* motion, which is effected by a successive contraction of their fibrous coats. Here the minute mouths of the lacteal vessels, opening on the inner surface of the small intestines, take up the chyle, and carry it, as has already been described, to the receptacle of the chyle, and then by a duct running up the chest along the spine, called the thoracic duct, it joins the blood-vessels. The refuse of the aliment which has not been taken up by these lacteal vessels passes on through the large intestines, and at length is ejected from the body. Digestion is not brought about, as has by some been supposed, by any mechanical means, as by the grinding powers of the coats or sides of the stomach, nor by heat alone, nor fermentation, nor by the simple resolution of the food into a fluid; but it is evident that it undergoes a series of chemical actions in the stomach and bowels, whereby its nature and properties are completely changed; and thus animal and vegetable substances, however different, are reduced to one peculiar kind of fluid, the chyle, which, though it may be found to vary slightly according to the kind of food, is, in its general properties, always the same. The gastric juice varies in different animals. In those which feed on vegetable matter, it dissolves these substances only; whereas grain and vegetables pass through the stomach of a purely carnivorous animal *without* undergoing any change. The gastric juice *has this singular* property, too, that although it readily *dissolves* dead animal matters, and reduces them in a short time to a thin pulp, it will not usually a living fibre; so that, after death, the coats of mach have been found dissolved into holes, same juice, which, in the living body, had no suc This forms a most important fact in medical j dence. A stomach of some kind or other is all animals; for it is by this organ that nutri growth are solely promoted. There are sm simply formed animals whose whole body co an oval hollow bag, or stomach, with a simp for the mouth to take in nourishment, and n organ whatever. The common polypi have mouth and hollow stomach, with several tenta arms, by which the creature seizes the wor grubs on which it feeds; these it swallows, a their juices, and then voids the remainder f mouth. The common leech has its whole body into a number of small cells, like a piece of hone and these receive the water, and sometimes bl which it feeds. Flesh-feeding animals have a bag for a stomach, and their food is easily a digested. Those animals, again, that feed o which is of more difficult digestion, have three stomachs, into which the food successively pas it has been masticated or chewed a second tim mouth. This is the case with cows, sheep, d Birds that feed on grain have first a sap-bag, into which the food enters, and remains fo siderable time, mixed with a juice somewhat lik here it is softened and rendered moist, prepar its passing into the true stomach, or gizzard, an extremely strong muscular bag; in this, assistance of a number of sharp-pointed pebbl such birds always swallow, it is ground down a on by the gastric juice. This compensates for ciency of teeth in fowls. Crabs and lobsters teeth in their mouths; but in their stomach found three or more teeth, which assist in grind the tough sea-weed on which they feed. By tication, the qualities of the gastric fluid ma changed, that animals accustomed to live on flesh will exist and thrive on a vegetable diet, the case with dogs, and many birds. All the liarities in the natural history of animals illus least directly, the uses of the digestive organ human being.

THE LIVER, &c.

The Liver.—Opposite the stomach, on the ri lies the liver, a large flat substance, of a dar colour, divided into two lobes. The liver has convex upper surface, and is hollow or concav it is also thick and solid at the back part, and becomes thinner towards the front, where it a portion of the stomach and bowels. It is s in its place by several ligaments attached to rounding parts. In the under side of the li small hollow, is situated the gall-bladder, a s bag which contains the bile. A tube from this called the bile-duct, passes into the upper p the bowels, carrying the bile there. The liv plied by several branches of an artery in the u that the other organs are, but it has also a p which no other organ of the trunk possess large veins, which return the blood from t part of the bowels, before going to the hea the substance of the liver, and there spread numerable branches throughout its whole From this venous blood the bile is suppos secreted, and after having yielded this subst vessels collect again into one large trunk, the large vein which carries the blood to t The liver weighs, on an average, from thre pounds weight, and the quantity of bile wh cretes, taking into account its large supply must be very considerable. The greater p of animal beings are provided with an app some kind or other for preparing a supply and in many the liver bears a large proport

contents of the belly. In some animals, as the e, the gall-bladder is wanting, there being merely es to convey the bile into the intestines. In the st classes of animals, all traces of liver or gall- disappear.

Spleen.—This substance is situated below the ach, on the left side, betwixt it and the ribs. It shape a flat oval, and of a dark iron colour. No ar opening has been discovered proceeding from e has its use been as yet accurately ascertained. ssibly serves to relieve the stomach of its surplus city of blood while this organ is distended with ; and the splenic vessels have also been held by to contribute to the secretion of the gastric juice. ypleen, it is remarkable, has been frequently cut from living dogs, without causing any apparent agement in the health or digestion of these animals.

Pancreas.—This substance, known under the e of the sweet-bread, is a large oblong gland (or ivary organ), lying across the back part of the belly, ading between the spleen and the middle of the . This gland pours out a substance something the saliva or spittle of the mouth; and by means small duct or canal, empties it into the upper s, along with the bile from the gall-bladder, both e substances aiding in digestion, and the prepara- of the nutritious fluid to be afterwards mentioned.

Lacteal Vessels.—These are innumerably small tubes, eeding from the ileum or small intestines, along whole course, and spreading along the mesentery, re they form an immense number of small knots, ands, by joining together. These are the vessels h take up the fluid chyle, or milky-like substance, it has been digested and properly prepared in the mach and bowels. From these mesenteric glands, chyle is conveyed by these ducts or canals to an- r large gland, situated in the loins, on the right side the aorta, and immediately below the diaphragm, d the receptacle of the chyle. From this recep- the thoracic duct arises, and passing upwards by side of the aorta, or great artery of the body, it joins left subclavian vein, lying under the left clavicle llar-bone, and thus pours the whole of the chyle the general circulation.

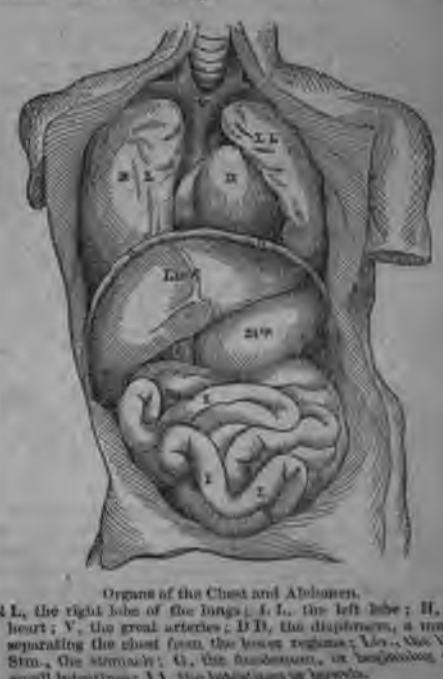
The Kidneys.—These are situated in the loins, one each side of the back-bone, about one-third up the e. They are in shape somewhat like a French bean, their internal structure consists of a number of mi- e porous tubes. They each at the middle hollow part ive a large artery, and their use is to filter from blood the superabundant fluid, and salts and juices ecessary for the system, and transmit these, by ans of two small tubes, called the ureters, to the nary bladder. These tubes enter the back part of the dder in a slanting direction, which serves the purpose alves, preventing a flowing back of the fluid when the dder is full. The bladder is situated in front, imme- ely above the bone of the pelvis, called the pubis.

The whole cavity of the belly is lined by a thin mem- ne, called the peritoneum, which is double, being ected from the sides of the cavity over the whole of intestinal organs. This peritoneum is liable to in- mation, in the same manner as was mentioned of pleura, which produces a very violent disease. The e of the intestines, too, are also subject to the same ction. Dropsy may arise from water being formed ween the two folds of the peritoneum.

The Lymphatic Vessels.—These are another distinct of vessels spread over all the inner cavities of the y, and also throughout the skin, on which they open innumerable small mouths. Their office appears to o take up from the blood a thin lymph, which they vey into the receptacle of the chyle and thoracic duct, also to exhale or carry off from the skin the super- us moisture of the body. This moisture forms the at, and several pounds of fluid are daily drained off m the body in this manner, even when little or no ily exercise is taken, for perspiration continually s on insensibly. These vessels are composed of a series of extremely small tubes, and, joining and inter- weaving, form numerous glands, especially in the groin, armpits, and neck; when swelled by disease, they harden and enlarge, forming knots like a pea or bean. But they are no less numerous on the surface of the inner cavities of the body as on the skin; they are found in the brain, on the surface of the lungs, where they give out a large proportion of vapour at every expiration of the breath, and in the abdomen or belly. It is a disease or sluggishness of these vessels, whereby they do not perform their necessary duty of taking up all the super- abundant fluids, that causes accumulations of water in the chest, belly, and legs. The branches of the lym- phatics of the lower half of the body join the receptacle of the chyle; those of the upper part enter the thoracic duct just before the latter pours its contents into the subclavian vein.

THE BOWELS.

From the lower or pyloric orifice of the stomach, the duodenum, the first portion of the intestinal canal, takes its origin. This gut passes below the liver and receives the bile-duct, and the duct from the pancreas, when it terminates in the jejunum, which again passes into the ileum, or principal portion of the small intestines. These are of great length, and occupy a great part of the abdomen, being folded and twisted backwards and forwards in many intricate windings. At the end of the ileum, the colon, a large gut, makes an arch upward towards the right side, and across the belly, and descending at the back part, ends in the short bag, called the cæcum, which joins the rectum, the termination of the intestinal canal. The whole length of the intestines in man is generally about six times that of his average height, or from thirty to thirty-six feet. In all animals that feed on vegetables, the intestines are of great length; whereas, in those that derive their nourishment from animal food, they are of much shorter proportions. Two membranous substances, called the omentum and mesentery, run along nearly the whole length of the intestines, and serve as a means of their attachment and proper suspension in their places. The bowels have three coats—an external one, common to them with the other viscera, a muscular coat, and an internal mucous covering.



Organs of the Chest and Abdomen.

R L, the right lobe of the lungs; L L, the left lobe; H, the heart; V, the great arteries; D D, the diaphragm, a muscle separating the chest from the lower regions; Liv., the liver; Stm., the stomach; G, the duodenum, or beginning of the small intestines; I I, the intestines or bowels.

of sight, and is a most beautiful and ingeniously constructed object. The eye may be compared in its structure to a telescope, the purpose of both being to collect the rays of light proceeding from the surface of bodies, to concentrate these rays, by means of a refracting lens, into a focus, and, therefore, to form a very small image or picture of the object before them. The human eye is placed in a large hollow or socket in the upper bones of the face, surrounded by fatty substance, and the various muscles necessary for moving the eyeball and eyelid. At the upper and outer angle of the eye-socket is placed a gland, which secretes the tears that serve to moisten the delicate surface of the eye, to wash off any dust or other substance, and to keep the eye continually wet and transparent, for the purpose of perfect vision. The tears, after spreading over the eyeball, collect at the inner angle, where, at each corner of the eyelid, both above and below, there is a small opening visible, which carries the tears down a passage into the nose. The edges of the eyelids are also supplied with glands, which pour out a mucous that prevents them from adhering together; and these, when irritated and inflamed, are often the seat of disease. The membrane which covers and imparts the white colour to part of the eyeball in front, is called the sclerotic coat. The middle transparent part of the eye in front is called the cornea, which is filled with the aqueous humour of the eye. Immediately behind the cornea is seen a circular fringed-like substance, which varies in colour in different individuals, being blue, black, hazel, &c.; and hence it is called the iris, or rainbow curtain. This iris has the property of opening and closing, according to the quantity of light which falls upon the eye; and thus the pupil, a black circle contained within the iris, is enlarged or lessened. Behind the iris is situated the crystalline lens, in shape resembling the small lens or ground glass of a common telescope, but of unequal swell on each side, being more flattened before than behind. This lens is contained within a capsule, or thin covering of delicate membrane. A familiar example of the lens of a fish's eye is presented every day in that white globular substance found in such eyes after boiling. The heat coagulates the lens, which is of the same nature as the white of an egg; and in the fish it is nearly a circular body, to adapt the animal's vision to the dense

by the sight of food when the appetite is good. f essential service in moistening the food, and ng it for the process of digestion in the stomach. nsation of taste is in all probability diffused every class of beings, however low in the scale ence, although it is probable many animals pos- le of it in their mouths, especially when these med of hard, horny, or even earthy substances, any insects—the lobster, crab, &c.—and where an corresponding to a tongue is wanting. Even irds that feed on grain and hard bodies, not er broken down in the mouth, must have little n of taste.

h.—The sensation of touch is diffused more or r every part of the body, but is most perfect at nts of the fingers, which in man are generally examine the figure and texture of bodies. For rpose they are furnished with a large supply of inute blood-vessels and nerves. It would appear re are different nerves that convey the sensa- touch, distinct from those which are the nerves ion; and that these proceed in pairs from the marrow; and that, moreover, the sensation of cold may be perceived very distinctly, in cases the pricking of a needle or contact of other is never felt. The sense of touch may be said ng to every animated being, and is one great eristic of animal existence. Vegetable bodies a certain degree of life, and show what is irritability of their fibres; but they have no n, properly so called; they are not sensible or injury, as the lowest and simplest sentient is; neither have they the compensating per- s of pleasure. It is probable, however, that n is not by any means equally acute in all ani- some feel more intensely than others, and it is y provision of nature that it should be so. The insects and reptiles, from their structure and are continually exposed to injury; and did they as acutely as the larger animals, the degree of suffering throughout nature would be excessive. animals bear the loss of limbs with impunity, ve the power of restoring these lost members in short time. It is probable that, according to fection of the nervous system, is the acuteness al sensation.

hus reviewing the different parts of the human t will be observed that most of its organs are On a line being drawn in the middle, on each ll be found parts which are exactly similar to responding side. This is the case with the brain, is a double organ, having two series of nerves ding out from each side of it to go to the respec- es of the body. There are two eyes also, each ng a distinct image on the retina; yet the nerves unicate so that only one impression is conveyed sense. The arms are double, to suit the various es for which they are employed, and so are the imbs, an essential requisite for the support of ly, and for progressive motion. The lungs, too, said to be double, having two distinct lobes; sometimes happens that one of them is entirely or diseased, and yet the important office of tion is still carried on. The stomach, the liver, me of the other viscera of the abdomen, are, r, single, their several offices being common to ole body.

THE HAIR AND NAILS.

hair grows out from the skin somewhat in the r of a vegetable production. Hairs are fixed by n the skin, from whence, by a series of minute , they draw nourishment, and continually in- in length. They possess no sensibility, however, like the other parts of the frame, may be cut off t producing the least pain. Hair is of different in different individuals—is fair in those of light xion, and deep black in the swarthy. In old age ches, and even in many young persons, where

there is a particular disease in the hair, or dryness in the skin, this colour changes to grey and white. The colouring matter of the hair is contained in the centre, which is of a hollow form, and consists of an oily substance, in which carbon or charcoal, in minute particles, is more or less mingled. The nails are somewhat like hair in their production and composition; they are, like hairs, insensible to the touch, and may be cut or pared without producing pain. They receive nourishment from the blood-vessels of the extremities, and have a constant growth or renewal of their substance. Nails serve as a defence to the tender parts of the fingers; in animals they form formidable weapons of attack. The horns of cattle are exactly of the same nature as nails, and are chiefly composed of animal gelatine.

The manner in which the various secretions take place in the system, that are to form hair, nails, wax for the ears, blood, perspiration, &c., cannot but excite our admiration; for the whole is a chemical process of the most perfect kind, and such as art possesses no power to imitate.

THE SKIN.

An external compact membrane or skin covers the whole body. The outer skin, or cuticle, is unprovided with any blood-vessels or nerves, and consequently is insensible; in this manner it is well suited for a protection to the parts beneath; it is pierced by innumerable minute pores, which are the mouths of the exhalant vessels: it is thicker in the palms of the hand and soles of the feet than in any other parts of the body. Below the outer skin is a thin membrane, called the *rete mucosum*, which, assuming different hues in different nations, gives rise to the variety of colour in the human race. Some have held this membrane to be double, but this is not established. In Europeans it is white, passing into yellowish brown; in native Americans, of a copper colour; in Negroes, of a deep black. The common belief is, that climate has the effect of modifying the colour of the skin, as the black skin only occurs in tropical regions, and it is found that there it is a protection against the scorching influence of the sun's rays. Negroes will remain cool and comfortable exposed to a sun which would be intolerable to a white-skinned person. Their free perspiration seems to be of great service. Immediately below this network is the *cutis*, or true skin, an extremely sensible membrane, so thickly studded with minute blood-vessels and branches of nerves, that the smallest-pointed needle cannot prick it without touching many of them. On the points of the fingers, lips, and other parts of the body, these vessels are very numerous; and hence these parts are endowed with exquisite feelings of touch. Below the skin is situated the cellular membrane, which is a network, whose interstices are filled with fat, and it thus serves to fill up the spaces between the muscles, and to make up the shape, and preserve the symmetry, plumpness, and beauty of the whole frame. In cases of emaciation, this fatty matter is sometimes entirely taken up by the absorbent vessels—as after a tedious fever or other lingering disease—when the rough outlines and indentations of the muscles, and the projections of the bones, become painfully apparent.

SLEEP.

The various functions of the body are divided into voluntary and involuntary. When we eat we perform a voluntary motion, but digestion is performed without the action of the will, or is involuntary. The whole interior functional operations are involuntary, and go on whether we are awake or sleeping.

As a constant supply of food is necessary to repair the waste of the grosser parts of the body, so sleep is essential for the repose and renovation of the finer and more subtile nervous energy. Mere rest alone will not recruit the animal frame, but sleep, or a profound oblivion of feeling and sensation, and of every external circumstance, seems essentially necessary at every periodical revolution of the day. Toward th a day of exertion, the muscular powers wh been employed in motion, and in sustaining erect, begin to suffer particularly; the eye dim and heavy, and the eyelids close involunt lower jaw falls down; the circulation of through the lungs is sluggish, hence frequ ing is caused; the head nods forwards; all objects affect us less and less; the thought confused; and at last the profound oblivio ensues. We are unconscious of the exact when we pass into sleep, but occasionally it that immediately afterwards we are awaked vulsive start, which is caused by the sudden in of the powers of volition, when as yet but imperfectly lulled to rest. Sleep is quite es existence. Deprive a person of sleep, and sinks under the privation more rapidly th famine. Indeed, no circumstances, however will prevent the approaches of sleep for any time; and under the severest calamities, and e in the hour of battle, or when suffering from fatigue, or cold, or hunger, sleep steals upon w the senses in oblivion. Healthy sleep is so pr to resemble, in all that regards self-consciousn itself. Sometimes, however, the mind exert vity, though it is but a partial exertion; a dreams, or thoughts of sleep, are made up of gruous associations, such as thoughts of the and incidents of long bygone years; scenes experience, and others totally imaginary, mixed up and jumbled together. In sleep continues to beat with regularity, and the q of the blood is carried on throughout the body; perform their functions, the stomach digests bowels, and all the glands for secretion, carry operations; in short, every thing is carried on with the sustenance of the body and the ex the vital powers; but for the most part all othe such as those over which we have a contr waking hours, are at rest. This is not always however, as walking during sleep, or somna is a peculiarity to which some individuals Dreams are most common when the sleep is or too long continued, and thus they occur towards morning, or through the night, if th is loaded and oppressed with food, or the mind and deeply impressed with cares and solicitu state of health and serenity of spirits, the most and most refreshing sleep is during the first the night. When asleep, the circulation and are both somewhat slower than when awake, animal heat becomes diminished; and this is why more clothing is required in bed than d day. This is the reason, too, why a person l to sleep out of doors, or on a sofa, with the u ance of clothes, feels chill and uncomfortable ing. Digestion, too, would appear to go on rously during sleep; and hence the impropriet to bed with a full stomach. During the darkness is the most natural and obvious tim for repose, and it is only the absurd encroac fashion that have well nigh turned day into n going early to bed, the damps and colds of avoided, which is of essential consequence, for the delicate. There is also a natural con the functions of the body with the periods o night, which makes sleep taken in the first p night peculiarly refreshing. The absence irritation of the head and other parts of the perfect rest of the mind and external senses great influence in promoting sleep. Again, a causes which weaken and debilitate the body, sleep; such as great losses of blood, cooling purgatives, coldness of the atmosphere; and such as opium and tobacco, drinking largely spirituous liquors, by first causing great e and afterwards a corresponding debility of th also predispose to profound and lethargic sle

disposition of woman:—"From the greater
f their frame, and from the numerous all-
nected with their temperament, combined with
tant familiarity with distresses which are not
, the sympathy of women with the sufferings
is much more lively, and their promptitude
ater relief, wherever it is possible, is much
r than in the generality of men. To the truth
mark every day's experience bears witness;
the testimony of travellers, it appears that
ation extends to women in all the different
ociety."

TEMPERAMENTS.

are certain conditions of the bodily frame
dently give rise to varieties of the human con-
and which have been called temperaments.
e been peculiarly the object of attention to
heim, and others of the phrenological philo-
As their views on this subject seem to us of
ar order, a passage is here extracted from
e journals devoted to that science. "Dr
n," says the journalist, "recognises four pri-
ardinal temperaments, to which he considers
dual cases may be advantageously referred,
pure, or much more frequently as consisting
more combined. I shall first give Dr Spurz-
ief description of them, and shall afterwards
pon each in detail.

e lymphatic, or phlegmatic temperament, is

exercise, have lost all trace of some other
ment which they may have possessed in youth.
ital characteristics of the lymphatic tempe-
re soon told; an insurmountable tendency to
, an aversion to exertion of either body or
m the hopeful traits. It is, therefore, obvious
estraining faculties, Cautiousness and (in some
ifestations) Secretiveness, are the only organs
operation of which it will correspond; while
her propensities, and the intellectual faculties,
nervated and restrained by it.

been generally supposed that the sanguine
on is produced by the perfection or relaxa-
the circulatory system; and it seems such a
supposition, that it is difficult for us to allow the

adaptation to external circumstances, analogous to the white hares and other animals of northern regions; but, if this is the case, it is difficult to imagine how it is that Laplanders should continue tawny, while the Fins, situated farther south, are fair. The most striking moral feature of the sanguine temperament appears to be a tendency to enjoyment of the present time, with little inclination to regret the past or to dread the future; and, in general, to look at either past or future no more than is accessory to happiness. The bilious temperament is characterised by a decided cast of features, complexion inclining to brown, dark eyes, and black or dark brown hair, with the muscles firm and well marked, and the figure, in general, expressive of vigour, with every motion significant and decided. In combination, it is frequently traced in a slight yellowness of the skin, which can only be detected by comparison, or an extraordinary acute perception of colours; for example, you may frequently find two persons, particularly ladies, the one with dark hair and eyes, the other with flaxen hair and blue eyes. The complexions of both would be denominated fair; on observing them near each other, however, it will be seen that the fairness of the dark-haired one differs considerably from the clear snowy whiteness of the sanguine.

With respect to the nervous temperament, it manifests itself in a remarkable quickness to learn and readiness of comprehension, but little tendency to sensual gratification, and an extraordinary power of passing from one subject to another."

MAN ADAPTED TO LIVE IN ALL CLIMATES.

Man has this superiority over all other animals, that he can inhabit every different region of the globe, however extreme the degree of temperature. He is found under the scorching sun and amid the arid plains of Africa, as well as in the frost-bound regions of Spitzbergen; and he is found to live and thrive under these different extremes, not only after a gradual naturalisation of ages, but can even move from one country to another, and undergo a vicissitude of climate with comparative impunity. Thus we see, even from our own country, emigrants going forth, and naturalising themselves very best for enabling them to live under extreme depression of temperature. The of hot countries, again, will be found livi fruits, and other vegetable substances, whic and genial soil produces in abundance, and their nature, are less heating and stimulati animal diet. In the intermediate and temper a mixed diet of animal and vegetable food i Much discussion has arisen whether man flesh-feeding or herb-eating animal; experie strates that he is equally adapted to become he will live on an almost purely animal diet on one purely vegetable; although, were w compare the form of his jaws and teeth, and structure of his intestines, with those anim on nuts and other fruits, and farinaceou substances, as, for instance, the monkeys, t proach of these to the human structure wo to us that at all events a farinaceous diet suitable to his natural organisation. We among all civilised nations that bread, and and mealy roots, in some shape or other, h a preponderance in every meal. But the art which man resorts to even in the first d civilisation, enables him to change the na various food, and to render it more suitab digestion and the purposes of nourishment gives him a wonderful superiority over all the animated world. Indeed, it is by thi mode of preparing his food, perhaps, as m original strength and perfection of frame, j other comforts of civilisation, that he is enab the vicissitudes of climate, and to prolong h longer period than the great majority of oth

Man has been formed with a naked sk evident intention that he should clothe him own labour and ingenuity. Almost all the more perfect animals have a covering of hair, or of down, which is at stated periods rene some animals in greater length and abunda ticular seasons, to suit the variations of te But man can always adapt his clothing to he inhabits, or to the varying alternations of

y have not only to acquire the words and their applications, but even to master the articulation s, with all their infinite combinations. The liberty, or that period when boyhood terminates hood commences, varies somewhat in different according to their high or low temperature; period may be reckoned about fourteen years; ween twenty and twenty-five, the growth of the erally terminates. About the age of thirty, be said to be in his full vigour, with his mental ly powers completely developed. Females arlier at a state of maturity than males: in warm females are full grown as early as their ninth year; in more temperate regions, about their or eighteenth year. The proportion of male born to that of females, is as 21 to 20; there a small superabundance of males; but, from causes, it so happens that there is generally superabundance of females actually existing ty. Among these causes may be mentioned, ter hardships and labours to which men are the effects of war, and, on the whole, the longer yed by females. This regular proportion of l female births throughout mankind in all ages, ll parts of the world, shows the admirable deprecision of an unerring nature.

OLD AGE.

ave seen that there is, within the animal frame, of operations, by which a constant supply of ment is afforded to make up for the daily waste ay, and that every part is constantly undergo renewal. To view a man in the full vigour then, we might suppose that, excepting accie was calculated to go on, in the course of e, for an indefinite period. The principle of ever, seems to have limits set to its duration, which it fails to keep in healthy motion the faculties. The apparatus of life is evidently but to last for a certain time. Old age creeps , and the vital flame burns fainter and fainter, t it sinks in the socket, and is seen no more. mmencement of decay is perceptible even in self. The child at first grows quickly, from and yielding state of all its vessels; but greese begin to thicken and get harder—a greater on of earthy matter is adding to the bones. tremities grow large, while the heart itself increase in an equal degree; hence the circ becomes less and less quick, till the period growth. When the growth of the body can no farther, a degree of fatness not unfreoccurs. This proceeds from the superabunrishment produced from the food, which, from etus or force of the circulation being more by the greater extension and resistance of , accumulates in the cellular textures and by of the extreme vessels. In every part of y, the induration produced by approaching omes conspicuous—in the bones now wholly in the skin, in the tendons, in the glands, in ries, and in the brain itself, which gets firmer er. Moreover, the arteries continue to get narrower, and even shut up in their minute s. At the same time, the nerves become more e callous and insensible to the impressions of es, and the muscles to irritation; thus, the conforce of the heart, and the frequency of its pulare diminished, and, of consequence, every ich impels the blood into the ultimate vessels. ality of humours is diminished in the denser he moisture which lubricates the solid parts ure manifestly decreases. Nor is the quantity ure only diminished; they themselves likewise vitiated. They were mild and bland in childhey are now acrid, salt, and fetid, and loaded reat quantity of earthy matter. This circumf the superabundance of earthy matter is evi- the gouty concretions in the joints of old people,

in different constitutions, the marks of old age begin to make their appearance. The skin becomes more lean and shrivelled; the hair changes to a grey colour, or baldness occurs; the teeth drop out, and, in consequence of this, the lower parts of the face, about the mouth and jaws, incline inwards; the muscular motions of the body become less free and elastic—this is especially seen in walking, old people generally treading on the whole base of the feet, and hence having a shuffling gait; the blood circulates slowly; the animal heat is diminished; the pulse occasionally intermits, and the whole energies of the animal frame become lessened; the eyesight begins to fail, and dullness gradually comes over all the senses; the memory undergoes a remarkable change—while recent events pass through the mind and make no impression, the occurrences of early life continually suggest themselves, and are minutely called to remembrance.

Although usually seventy years is the extreme period of human life, yet a small proportion of those born ever reach even this; a few rare instances occur where one hundred years or upwards are attained. The famous Parr lived to the age of 159 years; he married at the age of 120, and, when 130, was able to thrash, and to do every description of farmers' work. He was at last brought from the pure air and the homely diet of the country, into the family of the Earl of Arundel, in London, where he drank wine and lived luxuriously. The sudden change of diet and circumstances, however, proved quickly fatal to him. Henry Jenkins, another poor man, lived to the astonishing age of 169 years, and retained his faculties entire. Some time ago, a statement appeared of the ages of the resident pensioners of Greenwich Hospital, which contained at the time 2410 inmates. Of this number, 96 had attained to or passed the age of 80; one only was above 100; 15 were 90 or more; and 80 were 80 or upwards. About 42 of the 96 were of aged families, and in some of this number both parents had been aged. Longevity has in a great number of cases been found to be hereditary. Eighty of the 96 had been married; 79 were in the habit of using tobacco in some form or other, and 46 had drunk freely; 20 were entirely without teeth; 52 had bad, and 14 good teeth. But the oldest man in the house, who was 102, had four new front teeth within the two preceding years. The sight was impaired in about one half, and hearing only in about a fifth part of the number. Old people are not generally inclined for much exercise, nor is it suited to their stiff joints and impaired vigour; for the same reason they cannot endure much cold. Cheerful company, especially the company of the young, is peculiarly grateful to old people. Innocent amusements and recreations are also of great consequence, and the mind should be exercised in some useful or amusing pursuit. Cities, or at all events constant and agreeable society, are favourable to the condition of old age. In lonely secluded country places, the mind sinks prematurely into a total gloom and blank, for want of sufficient stimulus and variety to keep up the vigour of thought and play of fancy. Does death occur from what is commonly

The admirable structure of the body of a being—its superiority in every respect to the lower animals—afford a most perfect proof in the all-wise Creator, and is one of the most instances of the impossibility of our formation result of blind chance. Paley, after going over number of examples of this kind of design in proceeds to state that, in all "instances wherein feels itself in danger of being confounded by is sure to rest upon a few strong points, or upon a single instance. Amongst a multitude it is *one* that does the business. If we observe argument (he continues) that hardly two mind the same instance, the diversity of choice strength of the argument, because it shows the and competition of the examples. . There is a in which the tendency to dwell upon select topics is so usual, because there is no subject in its full extent, the latitude is so great, a natural history applied to the proof of an Creator. Perhaps the most remarkable in mechanism in the human frame are—the pi which the head turns, the ligament within the of the hip-joint, the pulley or trochlear m the eye, the epiglottis, the bandages which the tendons of the wrist and instep, the sin forated muscles at the hands and feet, the of the intestines to the mesentery, the coat chyle into the blood, and the constitution of as extended throughout the whole of the ani tion. To these instances, the reader's mem go back, as they are severally set forth in the there is not one of the number which I do decisive; not one which is not strictly mechan have I read or heard of any solution of these ances, which in the smallest degree shakes the sion that we build upon them.

The works of nature require only to be cont When contemplated, they must ever astonish greatness; for, of the vast scale of operation which our discoveries carry us, at one end intelligent Power arranging planetary syste at the other, concerting and providing an ap mechanism for the clasping and reclasping o ments of the feather of the humming-bird. proof, not only of both these works proce an intelligent agent, but of their proceeding same agent; for, in the first place, we can identity of plan, a connexion of system, from our own globe; and, when arrived upon our can, in the second place, pursue the connexi all the organised, especially the animated, bod it supports. We can observe marks of adap tion, as well to one another as to the element their habitation is composed. Thereby we p planned, or at least hath prescribed, a genera all these productions. One Being has been c in all."

OGY.—BOTANY.

iple, it may here be stated that the parent vege-
is charged with the function of liberating germs
eds, which vegetate as soon as brought into a sou-
n fitted for their growth. A seed is like an egg in
acter, for it possesses in itself that amount of nou-
ent which will enable it to subsist in the ground
g germination, or until it draws the means of
nce from the soil and atmosphere. Most kinds
eds, being contained in husks or shells for their
ervation, are able to retain their vegetative power
long period of time, if entirely excluded from hear,
and moisture; thus, on turning up soil which had
covered centuries ago, a new order of vegetation
ways observed to arise from the long-buried seeds.
may be further mentioned, as a provision in the
omy of vegetation, that, while each species of
s is incapable of being transformed by reproduc-
into any other, it is possible, in some instances, as
e animal species, to produce a hybrid or mixed
d, and, with the additional means afforded by culti-
n, plants and fruits may be improved in quality
very high degree. Thus, the common sour crab,
ing wild in our fields and hedges, is the uncultiv-
l original of the different varieties of the apple. Yet,
ntain this improvement, constant culture, trans-
ing, crossing, or grafting, are required. The plant
ly improved as respects itself, and if its seeds be
ed to grow up without culture in a poor soil, they
produce plants exactly resembling their humble
nal.

e term of vegetable existence, from the period of
ination till the final decay of the plant, is ex-
ely various: some plants are annuals, or grow but
ne year or season; while others are perennial, and
inue their growth from year to year; trees are
g the longest lived plants, some being known to
for upwards of two thousand years. The repro-
ive powers of plants are likewise very varied;
t may be stated in general terms, that in each case
re has provided effectual means of perpetuation,
r by means of roots or seeds, or by both. This
r of reproduction is strikingly observable in such
ts as the potato, which propagates by oviparous
pendent from the stalks, and by the tubers cling-
o the roots in the ground. In most instances, the
icial deprivation of the seeds before they arrive at
urity, incites the reproductive powers of the roots,
they increase in bulk, or throw up new plants at a
nce from the parent stem. When annuals have
ed their oviparous offspring (grain in the ear, for
nce), the object of their growth is accomplished,
they forthwith droop and decay.

he development of vegetable life is greatly dependent
ertain concurring agents, among which, in a parti-
r manner, are included *heat*, *air*, *moisture*, *light*, and
Each of these agents, however, is limited to a
range, and this range is different in different

so that excessive heat and excessive cold, and also the extremes of drought and of humidity, are always unfavourable to vegetation generally, though not to all kinds of vegetables. Thus some mosses and other plants, whose parts are few and little developed, continue to grow in very cold weather, and even under the snow; others, which generally contain much juice in their substance, but which are covered with an epidermis so compact that it resists the action of heat, and prevents any evaporation of the juice of the plant, live in situations where the heat is extreme, and during that part of the year when excessive drought renders the common vegetation as inactive as it is in polar countries during the depth of winter.

The condition of the atmosphere as respects temperature, moisture, and other qualities affecting vegetable life, is comprehended in the term *climate*. No two places at a distance from each other can be said to have the same climate, because each is subject to particular influences not affecting the other to the same degree. That district will possess the most genial climate, and be best adapted for the perfection of vegetable life, which at once lies most fair towards the sun, and is exposed to the action of refreshing rains, or is moistened in some other way. A free exposure to the sun throughout the year is equal to several degrees of latitude nearer the equator, other circumstances being favourable. The more free the exposure, the more readily will most plants blossom, and yield a rich fruit; so well is this understood in the grape countries on the Rhine, that the right bank of that river, which faces the sun, is reckoned to be much more valuable than the left, and commands a higher price for its wines.

The character of the vegetation in tropical and extreme northern and southern climates, is of the most opposite kind—the one luxuriant and continuous, and the other only for a short period during summer. In the tropical regions there is always about twelve hours of sunshine, and nearly the same length of darkness; and when the air is clear, the action of the sun is generally sufficient to occasion a suspension of the powers of many vegetables, or what is sometimes called *a sleep of plants*, during the heat of the day. But, unless for local circumstances, the chief of which are alternate successions of drought and rain, there is nothing in the mere solar action which can affect vegetation there very much more at one time of the year than at another; and therefore, considered with reference to the sun alone, the vegetation there is not only generally evergreen, but ever-growing, ever-flowering, and ever-ripe and in fruit.

In the extreme northern and southern latitudes, a portion of one half of the year is continual day, and a corresponding portion of the other half continual night; and when the continual day approaches, if part of the heat of the sun were not occupied in melting snow and ice, and turning into vapour the water which clouds the atmosphere and mitigates the ardour of the solar heat, the action of the sun in those high latitudes would at these times be excessive. As it is, vegetation, during the short period that it acts, is more vigorous in such parts of the polar countries as are out of the range of the cold produced by melting snow or ice, than it is in any other part of the world; and even in Lapland, we have the expansion of the bud, the blowing of the flower, the ripening of the fruit, and the preparation of the new bud, in little more than half the time in which these operations take place in the temperate climates. This state of things requires a suitable character in the vegetables placed in those countries—they must be capable of resisting equally the ardour of summer and the rigour of winter. For this purpose, such vegetables as stand exposed to the air at both seasons, form complete buds, encased in a hybernaculum, composed of a number of scales of a resinous or gummy consistency, with thin strata of dry air between them; and buds so shielded are proof against the utmost severity of cold. The more lowly plants of such places are defended by the snow which ground; and thus, though the action of th world is limited in its annual period, and number of species in which it is displa perfect in its system, and as secure in its as in the tropical regions. Between thes there is a regular gradation; and taking th observation along with us, we are in pos least the elements upon which a geograph may be formed.

While heat, variously modified, serves as citing cause of vegetable life, air and moistu are elements on which the vegetables feed The soil in which the plants have their roo atmosphere in which their branches and lea are the great laboratories of nature whence ments are drawn. To understand properly derive nourishment from these sources, it i to appeal to *chemistry*, or that branch of sci recognises the elementary properties of ma following are a few leading principles, briefly

"The substances which constitute the pri of every vegetable, are compounds of ca oxygen and hydrogen in the proper relative p to form water. Woody fibre, for example, i of such compounds of carbon with the el water. In another class of substances cont bon as an element, oxygen and hydrogen are sent; but the proportion of oxygen is gr would be required for producing water by t the hydrogen. The numerous organic acid in plants belong, with few exceptions, to this third class of vegetable compounds contain c hydrogen, but no oxygen, or less of that el would be required to convert all hydrogen i These may be regarded as compounds of ca the elements of water and an excess of hydro are the volatile and fixed oils, wax, and the re juice of all vegetables contains organic acids, combined with inorganic bases or metallic o these metallic oxides exist in every plant, a detected in its ashes." *

Nitrogen also forms a portion of most pla an important ingredient in the substan gluten, or the starchy material of farinace tables. It is chiefly drawn in the form of from the soil to which animal manures have plied. In general, carbon is the fundamental cipal element in plants, and this is derived el the atmosphere. The carbon exists in the at in the form of carbonic acid, or in a state of oxygen; and therefore, before appropriating bon, plants must necessarily decompose the at This process is actually performed by the kingdom. Plants possess the power of separ carbon of the carbonic acid from the oxygen, ing upon the carbon, return the oxygen to t sphere.

The process of decomposition and appro performed by the leaves and other green parts these constituting the breathing apparatus. the performance of this remarkable chemical a from the sun's light is necessarily required. vegetables are in a considerably darkened sta the day, and in darkness during the night, carb is accumulated in all parts of their structure; assimilation of the carbon and the exhalation o commence from the instant that the rays of strike them. As soon as a young plant breaks the surface of the ground, it begins to acquir from the top downwards, and the true form woody tissue commences. Plants thus improv by the removal of carbonic acid, and by the re oxygen, which is immediately applied to the us and animals.

The growth of plants, and their transform elementary properties in the soil and atmosphe

* Leibig's Organic Chemistry.

be regarded as a protracted and various process
chemistry of nature, proceeding on fundamental

In order that the process may not be defeated,
atmospheric air, and also the sun's light, must be
d in their proper proportions, independently of
vater. The air best adapted for robust vegetable
h is that of an ordinary density, near the sea's

Generally speaking, the more elevated the sta-
f the plant is, its action is the less, because the air
dense, therefore colder, and is understood to have
r evaporative power; but mountainous countries
nerally much better supplied with humidity than
; and therefore the dwarfed growth of plants in
situations must be considered as resulting much
from their diminished action than from any ex-
f evaporation. Hence, as we ascend the slopes of
ains which are of sufficient elevation for having
summits covered with perpetual snow, we find
them plants resembling those of a succession of
les, gradually getting colder than the mean tem-
ure of that which answers to the level of the sea,
same latitude as the mountain. So that, upon
ofty mountains near the equator, the Andes in
Peru, for example, we meet with something re-
ing the succession of plants in the whole quadrant,
he equator to the pole. But it is a resemblance
nd not an identity; because, although it be pos-
o find upon the side of such a mountain places
have the same mean temperature for the year as
d in every parallel of latitude, yet both the daily
ie seasonal distribution of the sun's action are
lifferent; and it necessarily follows that the
and even the characters, of the vegetables are
r so.

aid air supplies some vegetables with all the nou-
nt which, from their situations, they can possibly
; and therefore we may conclude that it is
e of affording some nourishment to every vege-

But the air also acts as a drain upon vegetables,
oving out of their structure a portion, and some-
a very large portion, of that water which is neces-
r the purposes of growth; and in proportion as
is more humid, it must perform this function
rfectly. We must therefore suppose that there
ertain degree of moisture, and of evaporative
jointly, in the air, which is best adapted to the
r action of plants; but what this is must depend
he nature of the plant, and must therefore be
ined by direct observation. Indeed, this is one
circumstances which tends to the local distribu-
the different kinds of plants, as we find them in
of nature; but, like the others, we cannot so
te it from co-operating causes as to obtain the
its action. There is one other circumstance con-
with the air which is worthy of notice, and that
ther it be more generally stagnant or in motion.
erfectly evident that the action of stagnant air
a plant must be every way less than that of
g air, whether we suppose the action to be of one
r another; and therefore, up to a certain point,
in the air must be favourable to the growth of
bles. Of this there have been proofs by direct
ation, in the same part of the world; and when
mine different parts of the world, we find proofs
are much more striking: thus, for instance, the
wind of the Atlantic sets constantly against the
of Brazil and Guiana, and up the valley of the
m, until its motion is gradually destroyed by the
mass of vegetation over which it passes.

Oriental isles, and the southern part of the
peninsula, are in like manner exposed to a con-
current of the air; and those two regions are, in
t of the number, the variety, the beauty, and the
y of their vegetable productions, the very gardens
two hemispheres. Even when the current of air
lternating one, the return of which is actually
urable to vegetation, such a situation is still
favourable upon the whole. Of this we have
g examples in the valley of the Mississippi, the
Malabar coast of India, and even in the British islands,
and, generally speaking, along the whole of the west
coast of Europe, where the advantage is not counter-
acted by some local cause.

Winds are therefore to be considered as performing
an important part in the economy of nature. From
northern and southern latitudes, where there is a small
supply of sun's light during winter, with weak vegeta-
tion, and consequently a superabundance of carbonic
acid in the atmosphere, the winds convey the delete-
rious material to tropical regions, where, by means of
the brilliant sun's light and strong vegetation, it is
readily and profitably consumed. Streams of wind in
a contrary direction, or from the equator to the poles,
in the same manner bring to us the superabundance of
oxygen produced from tropical plants. While heat,
moisture, air, and light, variously modified in the mul-
tifarious climates on the globe, produce the extraor-
dinary diversity of vegetable growth, another set of
circumstances affect the life of plants, and these relate
to the nature of the soil in which they are placed.
Although properly belonging to GEOLOGY, we shall pre-
sent a short exposition of what soils usually consist.

The soil is mainly composed of particles which have
been disengaged by various means in the course of time
from the rocks on which it rests. In some instances,
and more particularly on hills, it is composed chiefly of
pulverised materials from the rocks immediately at
hand or beneath; but in many others, the pulverised
matter has been washed down from high into low
grounds, or transported by floods from great distances.
The action of the air and water on rocks in dissolving
them, and the power of the latter element in transport-
ing the disengaged particles, are the principal causes of
the present arrangement of the soil.

Notwithstanding the different appearances which the
earthy covering of the globe exhibits, it is composed
almost entirely of four substances, formed by an original
union of simple elementary matters. These four sub-
stances, washed at a former period from rocks, and
more or less compact from influencing circumstances,
are called primitive earths, and are named *clay*, *sand*,
lime, and *magnesia*. Clay is variously named alumine
or argillaceous earth; sand is sometimes termed silex,
silica, or silicious earth; and lime is commonly called
calcareous earth. The distinctive characters of all these
substances are well known. Besides these four earths,
which either in a soft or hard state constitute the soil
and subsoil, the upper stratum or mould contains the
relics of decayed vegetable and animal substances, also
certain metallic bases, generally oxide of iron. The
particles of decayed vegetable matter, sometimes termed
humus, and known as food for new vegetation, are un-
derstood to be in reality a deposit of carbon gained by
plants from the atmosphere. Ammonia, as already
said, is also an ingredient in fertile soils.

The whole of these circumstances, modified in a
variety of ways, influence vegetable growth, and require
to be studied by the cultivator of plants. It has long
been remarked, that plants have a tendency to exhaust
the soil in which they grow, and to exchange their situa-
tion for one more suitable to their wants. The following
propositions on this subject have been laid down by two
eminent French chemists, Yvart and Pielet:—1. That
every plant has a natural tendency to exhaust the soil;
2. That all plants do not exhaust the soil equally;
3. That all plants of different kinds do not exhaust the
soil in the same manner; 4. That all plants do not
restore to the soil the same quantity nor the same qua-
lity of manure; 5. That all plants differently affect the
growth of weeds. From these fundamental principles
the following conclusions are drawn:—1. However well
a soil may be prepared, it cannot long nourish crops of
the same kind in succession, without becoming ex-
hausted; 2. Every crop impoverishes a soil, in propor-
tion as more or less nutritious matter is restored by
the plant cultivated; 3. Perpendicular rooting plants,
and such as shoot horizontally, ought to succeed each
other; 4. Plants of the same kind should not return

too frequently in a circle of cropping; 5. Two plants equally favourable to the growth of weeds ought not to succeed each other; 6. Such plants as greatly exhaust the soil, as grains, should only be sown when the land is in good heart; 7. In proportion as a soil is found to exhaust itself by successive crops, plants that are least exhausting should be cultivated. It may be added, that a successive change of crops has a tendency to destroy noxious insects, as those which are produced by one crop cannot be supported by another of a different description.

Nature, when unassisted, invariably makes an effort to change the crops of plants. When a forest in North America is burnt down by accidental fires in the summer season, trees of quite a different kind spring up from long concealed seeds in place of those which have been destroyed. When, in ordinary circumstances, one kind of plant has exhausted the soil in its neighbourhood, it pushes its roots to as great a distance as possible in quest of food, and there sends up shoots, while a new race of plants grows upon the spot which it has vacated. The seeds of certain plants, such as the dandelion, thistle, &c., are furnished with downy wings, by which they are rendered buoyant, and carried away from the parent plant by the slightest wind. The seed-vessels of other plants, such as the whin, when ripe, burst open with considerable force, and scatter the seeds to some distance from the place where the old plant grows. In these, as in a thousand other circumstances, we find that one of nature's great primary laws is that of perpetual change—an alteration from one condition and appearance to another, in endless succession and variety. In the artificial cropping of the ground, the farmer, for his own sake, is impelled to take a lesson from nature, and to study what species of plants he can most advantageously produce in succession from his fields. Hence, *aration*, or the *rotation of crops*, as it is differently termed, is a matter of first importance in husbandry.

A long course of experience and scientific inquiry have proved that all soils are capable of being improved by art, and supplied with restoratives suitable to the demands of the proposed vegetation. These artificial restoratives receive the name of *manures*, and are commonly in the form of animal excrements, these containing ammonia, one of the bases of vegetable structure, in greater or lesser abundance. Some idea of the powers of restoration from substances of this nature in a due state of putridity or decomposition, is obtained from the fact, that, from every pound of ammonia which evaporates, a loss of sixty pounds of corn is sustained. Potash, soda, gypsum, and other materials, also constitute manures, or bases whence are drawn fertilising principles in vegetation.*

CLASSIFICATION OF PLANTS.—LOWER FORM OF VEGETATION.

According to the latest researches of naturalists, about 80,000 plants of distinct specific forms have been discovered, but it is believed that as many more remain to be made known, and additions to the list are constantly taking place. For the sake of order and classification, as in the case of the Animal Kingdom, all plants, from the lowest to the highest forms of vegetation, are arranged in a progressive series of groups or families, the members of which possess a common resemblance, or are otherwise allied in character. This very necessary classification belongs to BOTANY—a term from the Greek, signifying a plant—and an outline of the plan adopted is given in the latter part of the present sheet. Here it is only necessary to mention, that, according to the Linnæan system, the whole Vegetable Kingdom is arranged in two grand divisions, namely, plants having visible flowers (*Phænogamia*), and plants having no visible flowers (*Cryptogamia*).

* To students who desire full information on this highly important branch of vegetable economy, and particularly all who are to be engaged in agricultural pursuits, we recommend the *careful study* of "Organic Chemistry," by J. Leibig; published by Taylor and Walton. London. 1840.

The whole are also divided into classes, orde and species, each species containing a numbe ties.

The lowest forms in which vegetables m appearance are those of the *cryptogamia*,* am are included the *fungi*, the *musci* (mosses), (liverworts), *lichines* (lichens), *algæ* (sea-w *filices* (ferns), &c. The fungi, which may be the very bottom of the vegetable scale, are o in a great variety of forms, and, among othe rooms, toadstools, puff-balls, the fungous dry mentation, mildew, and mould. We may tak mentioned as about the lowest in the group. most persons are aware, makes its appearan surface of various familiar objects—decayi fruit-preserves, cheese, and old shoes. It never on any thing which is new or fresh, but is alw binger of decay, and may be considered a f towards the decomposition of the substance into stituent elements. How vegetation should app secluded a situation as the inner cracks in chee a jar of preserves placed carefully away in a c or on the leather of an old boot in the remote co bed-closet, is at first sight incomprehensible; b sideration of the reproductive powers of fung explains the circumstance. The whole of the tribe possess the most extraordinary productiv Instead of propagating by the ordinary and cess of elaborating and throwing off seeds, they by the dispersal of their entire substance. E ticle in their mass is a germ, or technically which, though smaller in bulk than a parti dust, and generally so minute as to be invisible to the naked eye, is the embryo of a new plant, and will develop its powers of vegetation as soon as placed in an appropriate situation for its growth. In this manner, a toad-stool having performed its office and exhausted its means of nourishment, shrinks, dries, and dissolves in millions of atoms, which, being liberated and floated away in the atmosphere, are deposited in every imaginable Some are inhaled into the lungs of anim others enter into the fabric of trees and h in short, they find admission into every exp penetrable substance. It is, however, a distin ciple in fungous vegetation, that it can deve only in decaying bodies. Decay, or liability is necessary for its fructification; and when dition ensues, and other circumstances are the embryo expands and rises with surprising into notice.

Large fun

A very remarkable kind of fungous veg known to make its appearance in wine cellars stance which supplies the growth being the va the wine in the casks or bottles. If the cella and dry, the vapour escapes, and no fungous v is manifested; but if it be somewhat damp and from air and light, the fungous growth becom apparent. Round every cork a mould-like v will exhibit itself, and the vapour from the ca to the vaulted roof, will there afford nouris great festoons and waving banners of fungi wine vaults of the London docks, this kind fungi hangs like dark woolly clouds from the pletely shrouding the brick arches from ob On a small piece being torn off and applied to of a candle, it burns like a piece of tinder wine escape from a cask in a moist and ill-cellar, it will altogether resolve itself into substantial kind. A circumstance of this na

now be understood that mould is a fungous
n, produced by a previous deposit of germs in
e or on the surface of the object on which it
the proximate cause of its development is gene-
up, and, without this condition, the embryo
in a dormant state. Still, it may be asked, how
appens to have green mould at its very centre:
is, that the fungous germs floating in the at-
e had various opportunities of finding admission
article of diet. They may have been deposited
ass of a field; the grass was eaten by the cow,
germs were so lodged in the milk; or, what is
bable, the germs fell upon the curd, and there
ealed till a certain dampness in the cheese
their vegetative powers into operation. It is
wn that the exposure of curd for a day *in* the
ere will have the effect of producing cheese
mould. The mouldiness of Stilton cheese is
, we believe, by practising this device. Those

* Popular Cyclopædia of Natural Science.

table matter is an aggregation of an infinitude of plants either sucked up by a water-spout into the atmosphere, or overtaken while carried along by the winds, and brought down by the falling drops. On the stones by the side of brooks, we may sometimes observe a similar reddish colouring matter, which, if not caused by metallic ores, will generally be found to be a primitive kind of vegetation. When touched, it feels slippery, and on examination by a microscope, it is observed to consist of myriads of plants, each consisting of a small vesicle or globule, which, on arriving at maturity, expands, bursts, and liberates plants of its own species. This excessively humble plant is classed with the algæ, as being the nearest to it in character, although these plants are for the most part of a large size, and grow principally on rocks in the sea.

The object which nature has in view by the germination and dispersal of the algæ, mosses, and lichens, is clearly that of preparing the way for a higher order of vegetation. It cannot possibly escape our observation, that the tendency to vegetate is a power restless and perpetual. We hew a stone from the quarry and place it in a damp situation, on the ground or in a wall, it is all the same which, and shortly a green hue begins to creep over it. This is the commencement of a vegetable growth, produced by germs floated in the atmosphere, and being attached at random to the stone, have been brought to life through the agency of the moisture. Other stones equally exposed, but in dry situations, have also received a clothing of these germs, but circumstances not being suitable, they have not been developed: give the moisture, and they will immediately appear. We hew another stone from the quarry, and build it into the pier of a bridge, just within the surface of the water. Shortly, the same kind of green algæ will appear; but the wet being in greater abundance and more continuous, the growth will become more luxuriant. Instead of the simple green hue, we have the addition of long filaments resembling green hairs, which float and accommodate themselves to the water around. This kind of plants, which are known to naturalists as the confervæ, propagate, like others of the cryptogamia, by a rupture of their tissue, and the liberation of germs, which become plants of the same species. Of course there cannot be a doubt that all open ponds, lakes, and running waters, abound in germs capable of producing this green filamentous vegetation.

The inquiry may perhaps here be made—supposing that nature designs this species of growth to be a forerunner of a higher order of vegetation, how is that result to be brought about? To answer this, we must take an expansive view of the subject, and not confine ourselves merely to one department of science. Nature is incessantly working out vast ends by humble and scarcely recognisable means. It seems to be a principle that nothing shall remain stationary or unchanged. The whole surface of our planet is every instant altering in its features. Mountains are being washed down into the plains, rocks are mouldering into soil, the sea is filling up at one place and encroaching on the land at another, and water-courses are constantly shifting their outlines. The duty of filling up seas, ponds, lakes, and rivers, is consigned to divers means within the animal and vegetable economy, and one of these is the growth of algæ and other aquatic plants. Take a pond of water, and shut off its means of supply from rivulets and springs, and then observe what an effort nature will make to fill it up. The sides and bottom become speedily covered with a luxuriant crop of confervæ; other plants, which grow only in water, begin to make their appearance, their seeds being wafted thither by winds; at length the superficial matting of herbage is able to support the weight of birds, grass grows, there is alternate vegetation and decay, and finally the pond is filled up. This routine is observable in many small lakes which are fed by weak springs, and, except for an artificial clearing out occasionally, they would in a short time become *dry land*. What, indeed, are the extensive peat-mosses *but lakes* and pools choked with vegetable matter, which remains in a half-consumed condition. see that the green hair-like ooze which stones in the water, humble and apparent cant as it is, performs a distinct part in cessary to work out the important design dence.

Algæ.

The algæ are the vegetation of the deep, as immense forests in the rocky bed of the they furnish food for animals, and assist in and altering the channels. On being decomp afford an alkali to soap manufacturers, and s ingly useful in furnishing iodine, a substance now used in medicine for reducing glandu ings.

Lichens are a numerous family of plants, various appearances. Their usual aspect is crust of a grey or yellow hue, and their s place of growth is on old walls, gravestones yards, and rocks; they are also seen grow trunks of old trees. Their structure is ve

each plant consists of a membranous scale, divided into lobes, and they cling to the objec they grow by means of small filamentous ro insinuate themselves into the most minute Growing usually as parasites on some kind of stances, they derive their nourishment exclus the atmosphere, and only require pure air light, with a fair proportion of moisture, for sistence. Their whole economy being rudim simple, they are capable of living at great al mountains, where the air is too thin for the the higher orders of plants; on this account are found flourishing beyond the limits of e kind of vegetation, even to the very verge of snow. At these great heights they cannot be of any service in preparing soil for plants of order, but they at least help to bray down t beds, and level mountains with the ground. From the atmosphere they have the power o oxalic acid, which, acting chemically on th base, causes small hollows, sufficient to gather the atmosphere; and the moisture finding it crevices, the rock is split by frost, and in time into fragments. The tenacity with which th to their situation, renders it difficult to scrape stones by art; but as light and air are essent subsistence, they may be easily removed by them over for a short time with a turf or earth. root (*radix* in Latin) is commonly de-
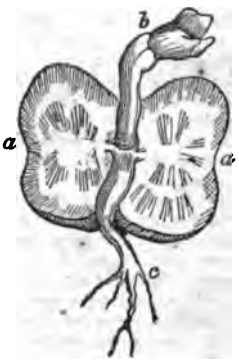
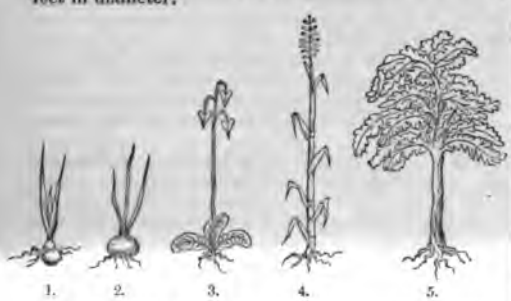
t part of a plant which attaches itself to
it grows, or to the substance on which
s the principal organ of nutrition. Ex-
his definition occur, as in the case of
es which grow floating loosely in water,
and others, having no root at all. As
ent of a plant is derived from the earth,
t part which grows in an opposite direc-
tion to the stem, and is buried in the ground. A root consists of several parts, which have been called the body or *caudex*, the collar or life-knot, the branches or radicles, when such exist, and the rootlets or small fibres, which seem to be indispensable in all roots. The body of the root assumes various forms; it may be globe-shaped, as in the turnip; conical, or tapering gradually from the collar to the attenuated fibre, as in the carrot; fusiform, or tapering at both ends, as in the radish; this latter may be abrupt, that is, as if the lower end had been cut off, exemplified in the devil's bit scabious; fibrous, or consisting of small thread-like fibres, which proceed directly from the collar, as may be seen in most grasses; tuberous, when the fibres bear globe-shaped bodies filled with starchy matter, as in the potato; fasciculated, when the fibres swell slightly in the middle; bulbous, when the round lobe consists of coats or layers, such as may be seen on cutting an onion across. A corm is similar in form to a bulb, but is not composed of layers; a palmated root consists of a number of oblong tubers proceeding from the collar, like the fingers from the body of the hand, as in the dahlia. Tuberous roots, such as the potato, are considered by some modern botanists as merely underground stems, from the circumstance of their having eyes, or buds, from which branches will spring. The crown, collar, or life-knot, as it is variously called, is that part which lies between the stem and the root It is the most essential portion of the whole; for, if it be removed or seriously injured, the plant will inevitably die; whilst the small fibres or rootlets, although an essential part of a plant, may be destroyed at pleasure so long as the crown remains, for it readily reproduces them. When it is of a slender make, as the seeds form, it dries up, and the plant soon dies. Such plants are termed annuals, as the poppy, mignionette, and others. The crown, however, in some cases, by proper treatment, may be rendered so strong that annuals can be brought to grow two years, when they are termed biennials; or for three years, when they are called perennials. The fibrous root consists of a quantity of long thin fibres, of different lengths and thicknesses, and having still finer ones springing from them, as in the case of wheat, barley, and most grasses. These small fibres or rootlets bear a resemblance to the branches and leaves of the stem. Fibrils consist of a central fasciculus of vessels, enclosed by a cellular cortex and cuticle. Like the leaves of trees that are not evergreen, they are annually produced; in some cases dying and falling off like leaves, in others becoming thicker, harder, and forming radicles or root-branches. The spongelets, as they are called, which take up nourishment from the soil, are situated at the extremity of these rootlets. They are minute spongy bodies, of an oblong shape. We have an instance of rootlets falling off like leaves in those arising from bulbs—such as the lily, the onion, the tulip, &c., which are pushed off and perish like leaves by buds containing the rudiments of the rootlets to be evolved next season.



Roots have a remarkable tendency to grow downwards, or in the direction of the earth's centre, and, from experiments, it is likely that this tendency is an effect of gravitation. The precise direction, however, is very much influenced by the condition of the soil. Both root and rootlets extend as if in quest of food, and this will penetrate sideways or obliquely to great distances. When plants are by any means prevented from fructifying by seeds, they almost invariably increase by extending their roots, from distant points of which new plants will spring up.

The stem or stalk.—When a plant shows itself above the ground, it evidently manifests a strong tendency to the light. Light, in fact, is essential in bringing it to maturity, and in giving the green colour to its leaves. The stem, with a few exceptions, is always above ground, and is the perpendicular pillar from which various lesser growths, such as branches, shoot off laterally. "The stem," says Rennie, "is divided from the root by the part called the crown or collar. The space between the collar and the first leaf or bud is termed the bole; but the great body of a stem is called the trunk. The stem of grapes, corn, and reeds, is termed the straw; the stem of palms, ferns, mushrooms, and sea-weeds, is termed the stalk; the stem of such flowers as the primrose, the daisy, the snowdrop, and the lily, is termed the scape, though flower-stalk is certainly better; the running stem, as in the strawberry and cinquefoil, is termed a runner; a shorter runner that does not root, as in the house-leek, is termed an offset; a longer one that does not root, as in the cucumber, a vinelet; and a small stem proceeding laterally from a root or stool, a sucker."

The stem, it will be observed, assumes many forms and characters as to bulk, structure, position, place, and duration. It appears as a tuber (*Gladiolus*, 1), a bulb (the onion, 2), a scape (*Dodecatheon*, 3), a culm (*Arundo*, 4), or as a woody column (the oak, 5). It varies in size from that of a bristle to a trunk of many feet in diameter.



1. 2. 3. 4. 5.

When a trunk bears permanent or perennial branches, the plant is termed a tree; when permanent branches arise, not from a trunk, but from the root, the plant is termed a shrub; when small and much branched, a copse shrub; when furnished with woody branches that are not permanent, as in the tree mignionette, it is termed an under-shrub; and when the whole stem is not woody, and dies down every year, at least as far as the crown of the root, the plant is termed an herb; when a trunk is formed like the underground stem of the iris, of the hardened bases of leaves which have withered and fallen, and is not taper, but all of one thickness, giving off no branches, as in the date and cocoa, the plant is termed a palm.

Buds, which have various forms, but are generally oval or roundish, consist of the young shoots either of leaf, flower, or twig, and proceed from what is called the axil of a leaf. They are usually formed either early in summer or in autumn, and are so contrived as to preserve from injury the delicate foliated structure within. The outside is composed of tough scales, which are frequently covered with a gummy resin, and they are internally kept warm by a downy substance interposed between the leaves. Buds are in most respects like bulbs, the scales being composed of cellular tissue, with distinct fasciculi running through it. This separation of the vascular fasciculi is the feature which distinguishes these scales from leaves. The inner scales perform the functions of leaves, until these are perfected and fully expanded, when they drop off; but in some trees, as in the apple and the almond, they are converted into leaves; whilst in others, as the rose, they are converted into the pellicles or foot-stalks of the real leaves, which spring out of them. When the central part of a bud contains leaves only, it lengthens upwards as it expands into a branch; thus a leaf-bud and a may be said to be the same. When it cont this is situated as in the bulb of the tu small bulbs are formed on the edges of the root between the scales, which gradually e expense of the scales, are detached, be bulbs, and send up leaves and flower-st respect to the manner in which the leaves they may be plaited, as in the palm and lil as in the rose and oak; embracing, as in the sage; double embracing, as in valerian double compound, as in carrot, mimosa, inwards, as in grasses; tiled, as in privet rolled outwards, as in rosemary, primrose, lengthways, breadthways, rolled from the base, or wrapped round the stalk.

The buds of trees, being in a state of grea and feeling the first warmth of the sun, th the continued shoot is roused into action; it moisture contained in the neighbouring ce with nourishing matter; the rising sap also vessels; it gradually swells, and bursting th scales, pushes into the light and air, unfoldin successively as it advances, until the whole tr green.

Leaves.—Leaves are the grand ornament and from their numbers, position, and delica nisation, they are designed to effect an impo in the vegetable economy. Springing from the and exposed in profusion to the atmosphere, form the functions of a breathing apparatus to that of the lungs or gills of animals. A sa pose, at least, is designed, for the circulati plants, like the blood of animals, requires to b to the atmospheric influence, in order that suitable for nutrition. This purpose is acc by the agency of the leaves, to which the sap, from the roots through the stem and branch pelled or attracted, and there both air and li cise their beneficial influences. Gaseous quali ever, are emitted as well as inhaled by the le that they allow the escape of aqueous fluid known. Leaves are thus indispensable to th of plants, and care should be taken not to inju for defoliation, either naturally or by art or instantly arrests the growth, and the failure nished expansion of foliage is a certain sig bility.

A leaf consists generally of two parts, the p leaf-stalk; and the lamina, or that part which and thin. Sometimes, however, as in the ro stipules are attached to the base of the peti leaf-stalk is that part which connects the leaf branch, and at the base will be found slightly l in which a bud rests. Sometimes the leaf-stalk ing, as in the sow-thistle and catch-fly, and in the leaf is said to be sessile or sitting. The la broad part of the leaf, is frequently of a differe on the under side to what it is on the upper. exemplified in the common silver-weed (*Potenti rina*), the leaves of which are hoary on the l and green on the upper. Leaves are either falling in summer; *deciduous*, falling in autu *sistent*, remaining till pushed off in the followin or *perennial*, when of still longer duration, as greens.

Some leaves are of a very remarkable shap none of the foregoing characters can descri most remarkable of these is the pitcher plant (*N distillatoria*), which is seen in the annexed e leaves of this plant are sheathing at the bas the end of the proper leaf is a petiole or stalk inches long, which is terminated by a bladder sel, furnished with a lid. This vessel is alw with water, which appears to be distilled from itself.

With regard to the manner in which leave from the branches, and their distribution woody cylinder to which they are attached, e

its colour. External vegetable glands are either without a foot-stalk; and all these glands are with the cells more regular than those in the of the leaf, and arranged in circles: a cord can generally be traced into the substance of d. Bristles are sometimes the excretory ducts s, as exemplified in borage, the nettle, &c.

rs.—A flower consists of several distinct parts, s, corolla, stamens, disk, nectarium, pistillum, pistacle. A flower is essentially constituted by ence of sexual organs, either male or female. here is only one of these present, the plant is unisexual; but more commonly these organs present in the same flower, which is in this med a hermaphrodite. In some instances, although the same plant bears both male and female it is not hermaphrodite, as these organs occur ent flowers; in others, again, the male and fewers exist only in different plants. Lastly, male, and hermaphrodite flowers are sometimes found together, either on the same or on different foot-Sometimes the male or female organs alone, d in a small scale, constitute the flower; but in they are surrounded and protected by the and calyx. All these are commonly borne on a led the peduncle (from *pedo*, to prop or support), which, expanding at its extremity, forms the receptorus, as it has been called, upon which the whole arts above-mentioned are supported. What is e berry in strawberries, appears to be nothing an the receptacle bearing the naked seeds or ice. It is called common when a number of rest on one receptacle. The round button exposed when the downy seeds are blown from l of the dandelion, is an instance of the common le.

alyx is the external leafy envelope surrounding er, and in which it rests as in a cup. Sometis entire, but more frequently it is divided into s (*sepals*), which are more or less separated ch other. It is most commonly green, but in wers it is highly coloured.

orolla is the true flower or blossom, and consseveral divisions or leafy parts, called *petals*, re almost all articulated at the base, and comly fall off at the earliest manifestations of matdecay. The extensive variety of tints in the g part of plants, is a remarkable circumstance table economy; and what may be the precise uch gaiety of colour, has formed the subject of hic inquiry. Independently of the exceeduty to the eye, which is certainly a matter for gratulation, it is believed that the lively are useful in attracting insects, these creatures tally performing an office in the reproductive y, and in carrying off saccharine exudations.

lower part of the single petal of a corolla is he claw, corresponding to the stalk of the leaf; broad part is called the limb. The corolla is tly furnished with certain appendages, attached o the throat or to the base of the petals, called s. These are placed in different parts of the ; in the common auricula they surround the the throat; in the ranunculus or buttercup ey appear like scales at the bottom of the claw; the monkshood, in the form of a spur behind olla. They receive the name of nectaries from position that they secrete honey, and they are found to contain a clear, sweet-tasted fluid.

ens, &c.—Within the beautiful corolla are several small filamentous objects, on some of are particles of fine coloured matter like dust. re parts of the reproductive organisation, and of stamens and pistils. In general, a stamen of two parts, in most cases of a filament (from thread), which is usually white, and always of er, which is usually yellow or purple. It has own that the stamens are always next to the that is, between their base and the base of the

seed-organ. It is upon the number and arrangement of the stamens that systematic botanical arrangements have principally been founded. The following are a few characteristics of the number, length, position, direction, &c., of the stamens. The number of stamens in each flower varies from one to twenty, or more. In length, they are equal or unequal, and this disproportion is sometimes symmetrical, sometimes not. In position they may be opposed to the divisions of the petals, or they may alternate with them. Sometimes they protrude beyond the corolla, at other times they are wholly included within it. Their direction may be erect, pendant, or horizontal, and their summit is variously inclined to or reflected from the centre of the flower. The filament which supports the anther is most commonly straight and filiform; sometimes, however, it is otherwise. It varies, from being as small as a hair to be large and flat like a petal, and its summit is either pointed or obtuse. On the summit is that essential part the *anther*, which is generally formed of two small membranous sacs, attached immediately to each other, or united by an intermediate connecting body. In form, anthers are subject to great variety, and, like the filaments, they sometimes cohere so as to form a sort of tube. Their colour is often yellow, orange, violet, white, &c., but never green or truly blue.

The pollen contained in the anthers consists of numerous regularly-figured small particles, which p different plants a very different figure, size, a The number of particles in a cell, which is ve sometimes amounts to many thousands. In som the pollen consists of transparent grains; in oth are of a white, purple, blue, or brown, and m quently of a yellow colour. When a grain of dropped into water, it swells and bursts, and quantity of matter escapes, which is supposed t fecundating principle of the pollen.

We may illustrate the action of the pollen from the anthers, by referring to the annexed small engraving. *a* is the filament or stalk of the stamen, *b* is the anther on its summit, and *c* is the pollen or dust in the act of being shaken down upon the stigma or upper part of a pistil, of which we observe three in a group.

In this figure, it may be remarked, that the is a roundish-shaped body, delicately poised on ment, and ready to vibrate and shake its dust o beneath or near it.

In the larger engraving, figs. 9 and 10, the parts of the flowering structure are combined, are frequently seen in nature.

Fig. 9.

a a Stamens. *b* Stigma, or Summit. *c* Ovary, or Seed-Bag. *d* Filament. *e* The style.

Fig. 10.

f Peduncle. *g* Calyx. *h* Corolla.

The pistil is a kind of tube with a communication from the stigma, through its style or stalk to the ovary or seed-bag beneath, and down this the pollen is permitted to exercise its influence. The seed-organ or ovary occupies almost always the inferior part of the pistil, and it is there that the process of fructification is fully effected. When cut open, it exhibits one or more cavities or cells, in which are contained the rudiments of the seeds or ovula; and it is in it that the change of the ovula into perfect seeds is effected. It is of various forms, but most commonly ovoidal. It is generally seated upon the receptacle together with the stamens, but frequently it is placed below the flower. Its cavity consists of one or more cells, in which the ovula or rudimentary seeds are found. It may be remarked, that the pistils spring from a nectary or disc in the centre of the flower, and surrounded by the stamens.

The precise mode of fructification is nowhere clearly stated. The stigmatæ are in all cases moistened with a clammy fluid, which causes the grains of pollen to swell, burst, and discharge their minute granules. Some suppose that these are taken up by spongelets in the summit similar to those of the root, while others allege that the fluid matter in which the granules float is sucked up. It has been discovered that the grains of pollen, when shed on the summit, in a few hours shoot out one or more delicate tubes, which by some philosophers are supposed to extend down as far as the seed-organs, and to expand around and between the nascent seeds. Some *believe them to* convey thither the granules, which at once enter into the tubes; others, however, deny that this is the case. The seed-organ lies at the base of the pistil, and contains the seeds either nascent or s to maturity. It bears a very strong resemblan egg-organ of birds and insects, and its parts cordingly received from naturalists the same names. The seed-organ is usually of an eg form, and is always composed of an outer m a middle membrane, and an inner membrane, mately united. As every seed derives its nou from the inner membrane, there must be a c cating point; and this point being always on t of the membrane, may be so termed; that on being termed the seed-scar, but popularly, th properly, named the eye. In some species t bears a number of smaller verges, to each o seed is attached, by means of the verge-cord stalk. All these parts are obvious in an unri bean.

Seed-vessels are various in form; as, for ex the case of the pea, fig. 11, the vessel is a she and in the case of the apple, fig. 12, it is the b fruit.

Fig. 11.

All fruits, in reality, are but so many vessel

for the seeds, and the various forms in which they
r are individually suitable to the purposes of their
l.

uctural arrangements.—Vegetable, like animal
ıres, are composed of solid and fluid parts.
f the latter are considered simple in their com-
n, as they contain more or less of a gelatinous
, which frequently imparts to them a consistency
ching to that of a solid body. The gum which
n see exuding from trees, is an instance of the
ty of vegetable fluids. Many of them, also, con-
ıinute globules of matter, which thicken them to
iderable degree. It has next been discovered
ıese often cohere and form solid masses, or unite
s so as to constitute fibres. These, again, collect
er, and compose various kinds of texture. The
arts of a vegetable are membrane and fibre, which
the tissues referred to, and their varied com-
ons in the bark, wood, pith, and medullary or
w rays. The fluid elements are watery solutions
soluble materials of the soil, which, by chemical
echanical agency, as well as the influence of the
ple of life, are decomposed, and again united in
nt proportions, so as to form new substances, or,
er words, the solid components, the textures, and
ions of the vegetable.

elementary parts of the vegetable structure ap-
o consist of minute bags, bladders, or vesicles,
ats of which are transparent membranes of ex-
tenuity. If a very thin slice of the stem of any
be put into a drop of pure water, and examined
microscope, it will be found to consist chiefly of
cells. Their size differs very considerably, from
he thousandth part of an inch to the thirtieth.
ugh in their original state they possess an oval or
ar form, yet, by being variously compressed, they
ade to assume other forms, such as twelve-sided
s, or six-sided, like a honey-comb, and pass by
ible gradations into the tubular structure. These
ıs modifications of the same elementary texture
received separate technical names, which, how-
it is unnecessary to specify. By the concurring
vations of modern botanists, these cells consist of
ate vesicles closed on all sides, and destitute of
or pore. It seems to have been satisfactorily esta-
d, that the partitions which separate them, how-
hin, must consist of a double membrane, formed
adhesion of the coats of the two contiguous vessels,
at the fluids gain access not by means of regular
ures, for none can be detected, but by exuding
gh the substance of the membrane. As from the
of the cells the coats cannot be supposed to unite
ry point, the spaces thus formed have been called
ellular passages, canals, &c., and they are supposed
form an important part in the function of nutri-
The nature of the matter contained in the cells
he intercellular spaces, differs according to the
in which it exists, and the peculiar powers of the
. Sometimes they are filled with certain liquids,
roducts of vegetable secretion; at other times the
nts are simple watery sap, and occasionally they
nly filled with air. Air-tubes and cells are most
ently met with in the centre of stems and in leaves,
r in roots, and never in the woody part of plants.
ugh some plants consist entirely of cells, yet, as
ly observed, the greater number of them have, in
on to these, numerous ducts or vessels, consisting
embranous tubes of considerable length, inter-
d throughout every part of the system. With
d to the origin of these, Dr Roget observes:
re can be little doubt, indeed, that the vessels of
take their origin from vesicles, which become
ated by the progress of development in one parti-
direction; and it is easy to conceive, that, where
tremities of these elongated cells meet, the parti-
which separate their cavities may become obli-
d at the points of junction, so as to unite them
ne continuous tube with an uninterrupted interior
re. This view of the formation of the vessels of
plants is confirmed by the gradation that may be traced among these various kinds of structures. Elongated cells are often met with applied to each other endwise, as if preparatory to their coalescence into tubes. Sometimes the tapering ends of fusiform cells are joined laterally, so that the partitions which divide their cavities are oblique. At other times their ends are broader, and admit of their more direct application to each other in the same line, being separated only by membranes passing transversely; in which case they present, under the microscope, the appearance of a necklace of beads. When, by the destruction of these partitions, their cavities become continuous, the tubes they form exhibit a series of contractions at certain intervals, marking their origin from separate cells. In this state they have received the names of *moniliform, jointed*, or *beaded vessels*. Traces of the membranous partitions sometimes remain where their obliteration has been only partial, leaving transverse fibres. The conical terminations occasionally observable in the vessels of plants also indicate their cellular origin."

Those parts of plants which do not exhibit the form of either membranes or cells, are comprehended in what is called the *vascular system*, which constitutes almost the entire bulk of the more solid parts of trees. If a branch be cut transversely early in spring, the sap will be found to exude, and cover the whole of the cut surface, which, if examined, will be found to consist of a vast number of exceedingly small fibres, vessels, or pipes, through which the liquid portions of the vegetable ascend or descend. These are, as it were, the veins and arteries of the plant. Indeed, whilst the tissue of cells above described may be said to constitute the flesh of plants, the tissue of fibres may be said to stand for the bones and other firm parts of the system. In animals, the fluids are conveyed to and from a central reservoir called the heart; but such an organ does not exist in the vegetable kingdom. The fluids enter by innumerable mouths at the root, and are conveyed by the vascular system to all parts of the plant fitted to receive them. There is little variation in the diameter of the vessels, and their general form is cylindrical. Their minuteness is quite astonishing. In a piece of oak of about the size of 1-19th of an inch, 20,000 vessels have been reckoned to exist. Hedwig measured the largest vessel in the stem of a gourd; it appeared 1-12th of an inch in diameter through his instrument, which magnified 290 times; so that its real diameter was the 3480th part of an inch. The vessels of plants do not, like those of animals, exist single, but are collected in bundles, or fasciculi as they are called, which sometimes contain hundreds of vessels. They occasionally also ramify; that is, some vessels shoot off from one parcel to unite with another, and afterwards return to that which they had left. By this ramification a reticulated appearance is frequently produced, especially in the bark and leaves of plants. They do not ramify like the vessels of animals from greater into less; but, by the division of a greater fasciculus into several smaller fasciculi, they at last become single, and thus their ramification is effected. It is generally supposed that they do not open into one another; that is, actually unite and be lost in each other, forming that kind of connexion which anatomists call inosculation or anastomosing (from a Greek word which signifies to open the mouth).

These vessels have been named according to the functions which they perform, or the appearances which they assume. There appear to have been two kinds of vessels discovered in plants, the straight and the spiral. Grew describes the former as straight hollow threadlets, fifty times finer than a horse hair, forming a larger tube, as if we should suppose a walking-cane composed of small straws. Leuwenhoeck describes them as composed, like the quills of birds, of two transparent tissues, one placed lengthways and the other across, with no lateral communication. It is the opinion of the highest authorities that both fibres and straight vessels take their origin from spiral vessels. The first is called the simple spiral. If the fleshy scale of any bulb, for in-

stance, that of the lily, be cautiously broken, and the parts separated, the spiral vessels will be observed like screws, partially unrolled. They consist of opaque silvery shining fibres, twisted in a spiral manner, so as to form a hollow cylinder, the spires being generally in contact. This hollow tube is sometimes formed of one continuous fibre, sometimes of several parallel fibres adhering together. The fibres are tenacious, and in some plants elastic. They differ much in size in different plants, and at different stages of the growth of the same plant. They stretch through the whole of its length, from the roots to the leaves and flowers, following the various curvatures of the stem. Grew found that they alternate with the straight vessels in every part of the wood, and surround and ensheath them in the leaf-stalk, the leaf, the flower, and the fruit. The straight vessels are said to be formed in spring, the spiral vessels in summer. These spiral vessels undergo various transformations. In many cases the inner fibres of the tube, instead of forming a continuous spiral, appear in the shape of rings succeeding one another at regular intervals, and constituting what are called annular vessels (from *annus*, a ring). This is considered a primary form of vessel, and, from the two simple varieties of vessels described, more complex forms are elaborated as the plant advances in age. In the punctuated vessel the spires are separated to nearly equal distances from each other, and the intervening spaces are filled up with a membrane sprinkled over with small obscure points or dots.

This is the largest with respect to the diameter of the vegetable vessels; it is at first transparent, but becomes opaque by age. A fourth variety of vessel, which has the same origin as the last, being formed of rings, is that in which the separations are not filled with membrane, but with small productions proceeding from these rings themselves. These ramifications often have the appearance of network, whence they derive the name of *reticulated* spiral vessels. It is impossible, in the present limited treatise, to go into a definition of the varieties and purposes of these vessels; and it will suffice to say that the spiral vessels, in all their variety, serve the office of conveying the sap throughout the whole of the plant. Besides the vessels already enumerated, vegetables contain certain organs denominated *glands*, which are composed of closely-compacted cells, and which perform the function of *secretion*; that is, the conversion of the nutritious juices into particular products required for various purposes in the economy of the plant.

Among the parts associated with or arising from the elementary structure already mentioned, are the pith, the wood, the bark, and the epidermis or skin. The pith is that soft, light, and spongy sort of substance which occupies the centre of the stem (hence sometimes called the heart), where it is commonly surrounded by a circle of vessels, which construct for it an appropriate canal. When seen in its most perfect form, it is found to consist entirely of cellular tissue, rather loose in texture, as in the alder, or compact, as at the knot of the ash. The wood (*lignum*) is that hard cylinder which immediately surrounds and envelopes the pith, and is enclosed by the bark. It is essentially composed of vessels, and of cellular tissue combined in an infinite variety of ways, and exhibiting every diversity of form. If a tree of several years' standing be cut transversely and examined, it will be found to consist of a number of cylinders, enclosing one another like so many layers or concentric circles disposed around an axis. By the number of these the age of the tree may be determined.

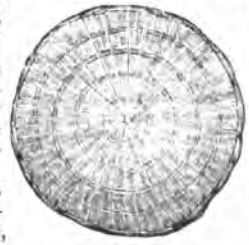


Fig. 13.

Fig. 13. is a section of a *stem five years old, having the pith in* the centre, *and a cylindrical layer* for every year of the growth, and the bark o side. The outermost layer, which is spong durable than the inner or heartwood, is called The whole are traversed by rays or lines from the centre of the stem to its circumfere are called medullary rays, or silver grain, an composed chiefly of large cells, extending tra or in the direction of the diameter of the composing by their union continuous verti the whole length of the trunk. They are c dullary (from *medulla*, marrow), because t supposed to be processes of the pith, or a co of it, which is not the case. Their use appe to keep open the communication between the the pith, which the formation of the wood wo wise have destroyed. The bark resembles w component parts, being made up like it of va cellular tissue, intimately connected with va As in trees a new layer of vessels is annually the wood, so a similar but much thinner lay made to the bark, to which the name of *liber*, bark, is usually applied, the old layer being pu wards. Between the vessels thus annually a considerable portion of cellular tissue is in the cells being commonly filled with juices. T is surrounded by an outer zone or envelope, the name of skin, epidermis, cuticle, or rind, given. It is an extremely thin membrane, an over the surface of every part of the plant, the spongelets of the roots, and the summit of in flowers. The rind of plants is similar to t animals in the functions in which it performs doubt, intended to protect the more sensib beneath. As the scarf-skin of the hand be durated by hard labour, so the rind of th exposed to a stormy climate, becomes rough, rind of the same species of plant, if reared in a situation, like the hands of a delicate lady smooth. As the plants grow, the rind stret sometimes to a considerable extent; but it which it is not easily stretched, as in the elm, up into innumerable cracks. The birch, and a trees, "cast their bright skin yearly, like th The rind is transparent and colourless where thin; but it is usually of a brown or grey co thick. Various opinions are entertained resp origin and structure of this membrane. Som phers hold it to be continuous with the formed of the outer sides of its cells. Other it as a separate membrane, composed of m or "bladders," as Grew calls them, which are dried up as the plant grows older. Th is now supported by the highest authorities. in some instances been found a very delic parent, and apparently inorganised, membr outside of the rind. Whether it possessed as they are sometimes termed, glands, w disputed point, but their existence has b incontestibly proved. They are a sort bags opening on the outside by an oval raised border, which contract when water is applied, and expand in dry air, or when sunlight.

Having already defined what constitutes cal elements of plants, as well as the nature which they derive from the atmosphere a thing more need here be said on the subj pass on to a short account of the methods b ascent and descent of the sap are effected.

The various matters held in solution b enter the plant in a perfectly crude state. rises in the stem of the plant, undergoing perceptible change in its progress, and is conducted to the leaves, where it experie important modifications. By causing the bibe coloured liquids, the general course of been traced with tolerable accuracy, and it traverse principally the ligneous substance in trees, its passage is principally through

alled the ascending sap; and after it leaves them, in rder to be distributed throughout the plant, it has been alled the returning sap. It still contains a considerable uantity of water, but a large proportion of that which as not been exhaled by the leaves, and its elements, xygen and hydrogen, has combined with certain other ubstances, so as to form proximate vegetable products, f which gum is the simplest, and generally the most undant. The returning sap descends from the leaves hrough two different structures. In exogenous plants, he greater portion finds a ready passage through the ber, or innermost layer of bark, and another portion escends through the alburnum, or outermost layer of he wood. With regard to the exact channels through hich it passes, the same degree of uncertainty prevails s with regard to those which transmit the ascending ap. De Candolle maintains, that in either case the uids find their way through the intercellular spaces; ther physiologists, however, are of opinion that partiular vessels are appropriated to the office of transmitng the descending sap. The nature of the forces which ctuate the sap in its descent from the leaves, and its istribution to different parts, as well as those powers hich contribute to its motion from the roots to the aves, are involved in equal obscurity. The hypothesis hat it resulted from capillary attraction, is now geneally abandoned.

SECRETION AND EXCRETION IN VEGETABLES.

The modifications which the returning sap undergoes, nd its conversion into gummy, saccharine, amylaceous, r ligneous products, are effected by the simpler kinds f cells. But there are other cellular organs in which reater changes take place in its nature, the agents for ffecting which are unknown, and are therefore referred enerally to the vital energies of vegetation. The proess is termed secretion, and the organs by which it is onducted, glands. The matter secreted is sometimes etained in the cells, and sometimes appears on the outide as an excretion, for the plant has the power of hrowing out by the root those superfluous or noxious natters which, if retained, would injure it. This exlains the fact why plants render the soil where they ave long been cultivated less suitable to their continuance in a vigorous condition than it originally was; nd also why plants of a different species are freuently found to flourish very well in the same situaion, where this apparent deterioration of the soil has aken place.

The vessels in which the fluid secretions are contained are of a peculiar kind, and exhibit ramifications nd junctions resembling those of the blood-vessels of nimals. We may also discover, by the aid of the icroscope, that the fluids contained in these vessels re moving in currents with considerable rapidity, as ppears from the visible motions of their globules; and hey present, therefore, a remarkable analogy with the irculation of the blood in some of the inferior tribes f animals. This curious phenomenon was first oberved by Schultz in the chilidonium, in the year 1820; nd he designated it by the term *cyclosis*, in order to istinguish it from a real circulation, if, on further nquiry, it should be found entitled to the latter appelation.

The circular movements which have been thus bserved in the milky juices of plants, have lately ttracted much attention among botanists; but considerable doubt still prevails whether these appearances fford sufficient evidence of the existence of a general irculation of nutrient juices in the vegetable systems f those plants which exhibit them; for it would appear hat in reality the observed motions of the fluid are in very case partial, and the extent of the circuit very imited. The cause of these motions is not yet known; ut probably they are ultimately referable to a vital ontraction of the vessels, for they cease the moment hat the plant has received an injury, and are more ctive in proportion as the temperature of the atmosphere is higher.

BOTANY.

Various eminent individuals have attempted the classification and naming of plants, each of whose arrangements is called a *system*, and possesses certain peculiar features. The three systems which have been most esteemed, and wholly or partly adopted, are those of Tournefort (1656—1708), Linnæus (1707—1778), and Jussieu (1699—1777).

THE SYSTEM OF TOURNEFORT.

Tournefort founded his system on the absence or presence, the figure, situation, and proportion, of the *corolla*. This part of the flower is always, when present, the most conspicuous and imposing, and attracted the notice of the earlier botanists, as it does that of children now, more than it really deserved; because, in fact, no part of the flower is more subject to incidental change than the corolla. He divided the vegetable kingdom into two principal parts, namely, herbs and trees; the primary divisions he subdivided into twenty-two classes, the first seventeen of which comprise the herbs, and the other five the ligneous vegetables; these are again separated into one hundred and nineteen sections, but without names or titles being applied to them, as in those of other botanists. The characters of these sections were not always sufficiently defined; and consequently the young botanist often met difficulties in arranging plants in their proper places.

Though now known to be imperfect, the system of Tournefort possesses great merit. His labours, considering the state of the science when he lived, were indeed great, and far surpassing those of either Linnæus or Jussieu. In fact, Tournefort was pioneer to both, and amassed, and in many cases assorted to their hands, the materials of which both their systems are formed.

THE LINNÆAN, OR SEXUAL SYSTEM.

The sexuality of plants had been discovered long before the time of Linnæus; but, as far as is now known, he was the first who suggested the idea of classifying plants according to the numbers, connexion, and stations of the male and female organs. From the moment the idea occurred to him, he was indefatigable in the completion of a system which, no doubt, he fondly flattered himself was founded in nature. His great acquirements as a scholar, his love of natural history, his station among learned men, and his connexion with many learned societies, eminently fitted him for achieving this great and laborious work.

The plan of the Linnæan system of botany was intended to comprehend the whole vegetable kingdom, which was arranged in two grand divisions, namely, plants having visible flowers (*Phænogamia*), and plants having no visible flowers (*Agamia* or *Cryptogamia*). The whole are included in twenty-four classes; and these classes are subdivided into orders, genera, and species. The terms used to express the classes are compounded of the Greek numerals and the word *andria*, signifying man. These classes are subdivided into orders, which are designated from their number of pistils by Greek numerals also, with the addition of the word *gynia*, which signifies woman. The following is a summary of the distinguishing traits of the respective classes:—

1. Monandria, with one stamen—Marestail.
2. Diandria, with two stamens—Speedwell.
3. Triandria, with three stamens—Grasses.
4. Tetrandria, with four stamens—Bed-straw.
5. Pentandria, with five stamens—Primrose.
6. Hexandria, with six stamens—Snowdrop.
7. Heptandria, with seven stamens—Water plantain.
8. Octandria, with eight stamens—Heath.
9. Enneandria, with nine stamens—Flowering-rush.
10. Decandria, with ten stamens—Pink.
11. *Dodecandria*, with eleven to nineteen stamens—*Agrimony*.
12. *Icosandria*, twenty or more, inserted into the calyx—*Rose*.
13. Polyandria, twenty or more, inserted in
ceptacle—Poppy.
14. Didynamia, two long and two short—Fo
15. Tetradynamia, four long and two short—W
16. Monadelphia, filaments combined in one
nium.
17. Diadelphia, filaments united into two sets
18. Polyadelphia, filaments united into more
sets—St John's Wort.
19. Syngenesia, anthers united into a tube
compound—Thistle.
20. Gynandria, stamens situated upon the sty
the germen—Orchis.
21. Monœcia, stamens and pistils in differen
on the same plant—Spurge.
22. Diœcia, stamens and pistils in separate flo
on different plants—Willow.
23. Polygamia, stamens and pistils united or
on the same or on different plants, an
two different kinds of perianth—Orache.
24. Cryptogamia, stamens and pistils not visibl

A more minute analysis of the system is as f

Flowers with stamens of a fixed number, and length.

First Class, or Monandria, having one sta
they have one pistil, they are of the first
Monogynia; if two pistils, they are of the seco
or Digynia.

Second Class, or Diandria, having two sta
they have one pistil, they are of the first
Monogynia; if they have two pistils, they a
second order, or Digynia; and if three, they
third order, or Trigynia.

Third Class, or Triandria, having flowers
three stamens.—If they have one pistil, they
first order; if two, they are of the second or
three, of the third order.

Fourth Class, or Tetrandria, having flow
only four stamens equal in length.—If they
pistil, they are of the first order; if two, of th
three, of the third; and if four, of the fourth
Tetragynia.

Fifth Class, or Pentandria, having flow
only five stamens.—Those having from on
pistils are named as in the preceding class
having five pistils belong to the fifth order,
gynia; and if they have many pistils, to the six
or Polygynia.

Sixth Class, or Hexandria, having flowers
stamens.—As they have one, two, or three pi
belong to the first, second, or third orders; if
six pistils, to the fourth order; and if many
the fifth order.

Seventh Class, or Heptandria, those ha
seven stamens.—If they have one or two pi
are classed as before; if four pistils, they bel
third order; and if seven pistils, to the fourth

Eighth Class, or Octandria, having flowers
eight stamens.—If they have from one to fo
they rank in the order corresponding to the

Ninth Class, or Enneandria, those having
stamens.—If they have one pistil, they belong
order; if three, to the second; and if six, to

Tenth Class, or Decandria, having only te
—If they have one, two, or three pistils, they
the first, second, or third orders; if five, to t
and if ten, to the fifth order.

Flowers with stamens of rather uncertain nu of fixed insertion.

Eleventh Class, or Dodecandria, having fl
from eleven to nineteen stamens inserted in
ceptacle.—If they have from one to five pi
belong to the orders corresponding to these
and if they have about twelve pistils, they bel
sixth order.

Twelfth Class, or Icosandria, having flo
twenty or more stamens inserted into the ca

Flowers of only one sex.

RT-FIRST CLASS, or Monœcia, having flowers, th pistils only, and some with stamens only, on plant. There are nine orders, taken from the and bundling of the stamens, as before.

RT-SECOND CLASS, or Dioecia, having flowers ils only, or with stamens only, on two separate f the same species. There are nine orders, as in the preceding class.

RT-THIRD CLASS, or Polygamia, having flowers h stamens and pistils, and also with only one of th on the same and on separate plants of the cies. There are three orders.

No flowers apparent on the plants.

RT-FOURTH CLASS, or Cryptogamia. Stamens and f present, cannot, from being very minute, be ed. The class contains five orders—Ferns, Mosses, *Musci*; Liverworts, *Hepaticæ*; Sea- *lgæ*; and Mushrooms, *Fungi*.

ne Linnæus added another class, or rather ap- which he called *Palmæ*, the flowers of which sufficiently known in his time to admit of their perly placed in the system. They are now ed into the various classes and orders of the ystem; they are still kept separate by Jussieu, as Linnæus did, arranged them into an order elves, under the old name. In fact, the genus is of all others the least associable with the plan of arrangement; being as distinct a plants in their structure, forms, and manner of as can be found in the whole vegetable king- till there were stations provided for them in al scheme, where they have been placed by ters; but, as already observed, they do not well with the genera among which they are For instance, who would imagine that the palm (*areca oleracea*) and the Scotch pine *ylvestris*) were any way allied to each other? Linnæan botanist must unite them, because wers are respectively monœcious, and their are united in one brotherhood.

THE JUSSIEUIAN, OR NATURAL SYSTEM.

uthor of this new system of botany has taken omprehensive view of the vegetable kingdom, been fortunate in fixing on those greater cha- ics of plants which distinguish them from each d which at the same time are the least vari- n examining closely the vegetable membrane, d it was either uniformly simple, that is, con- f tissues of cells of nearly equal size and con- or of tissues of which the cells were of various rmixed with each other, and formed into fibres straight or in spiral positions, and forming d openings of different structure and consist-

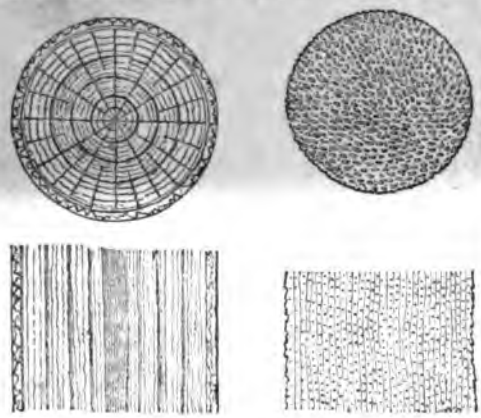
tion of Dicotyledonous and Monocotyledonous Plants.

his evident difference of structure served to e vegetable kingdom into two parts; the first d *Cellulares* or *Acotyledoneæ*, that is, plants wholly of cellular membrane, and rising from ds, or sporules, destitute of cotyledons or seed- Among these Acotyledoneæ are embraced the ades of the vegetable creation—the Filices, i, the Hepaticæ, the Algæ, the Fungi—being s it were, at the bottom of the scale, and ex- in their outward aspect as well as in their structure, nothing of that loveliness of form,

and but rarely that brilliancy of colouring, by which some of the other divisions of plants are distinguished. They are the first and rudest types of vegetable life, many of them consisting merely of a cluster of minute cells, or of minute threads, as in the case of *proto-coccus* and *byssus;* and many of them being, in fact, nothing more than a mere slime or mucus, as in the *moulds* and *nostocs*. Yet these minute and apparently insignificant tribes of vegetables, as already stated, are by no means useless or superfluous in the scale of nature.

The plants composed of the second description of membrane, Jussieu named *Vasculares* or *Cotyledoneæ*, because the organisation was more complicated, consisting of cells of various size, lying in various positions, in denser or looser laminæ or partitions, and being invariably fibrous; and, moreover, rising from their seeds furnished with cotyledons or seed-leaves. Of these, some presented one seed-leaf only, but the great majority presented two; hence the latter were called *Dicotyledoneæ*, and the former *Monocotyledoneæ*. This difference in the development of the seedlings of *Vasculares*, served as a basis for the two classes into which it is divided and named, as above stated.

But besides the difference in the germination of vascular plants, they also differ materially in the manner of their growth. The first class, *Dicotyledoneæ*, is annually increased in bulk by additions of bark and wood on the outside, hence it is also called *Exogenes;* whereas the second class, *Monocotyledoneæ*, is enlarged by the expansion of the interior parts of the stem, and therefore is also called *Endogenes*. These are very striking cha-



Sections of Dicotyledonous and Monocotyledonous Stems.

racteristics of the two classes, as regards their manner of growth; but there is another very obvious distinction, not only in the structure of their stems, but in their leaves. In a leaf of the first class, the petiole, or footstalk, is extended directly through the web or face, and is branched pretty regularly from the mid-rib (*costa*) to the margin; whereas in a leaf of the second class, there is no very conspicuous costa or mid-rib, the petiole being pretty equally divided at the base of the

Dicotyledonous Leaf of the common Apple-tree.

leaf into several branches, which run in nearly parallel lines to the point.

By these obvious distinctions in the man germination of the seeds, the modes of acc in the structure of the stems and foliage, the of *Cotyledoneæ*, or vascular plants, are clear But as there are great differences with res stations, connexions, and numbers of the flora of the plants included in this first division, of the system found it expedient, in order t the study of the science, to separate it, as alre into two classes; namely, *Dicotyledoneæ* and *ledoneæ;* the former being again separated subdivisions, namely, *Dichlamydeæ*, that is, pla flowers have two coats or coverings, the cal rolla being distinct; and *Monochlamydeæ*, that whose flowers have one coat or covering, the corolla not being distinct, but blended in one, plified in those of the mezereon.

Monocotyledonous Leaf of the Gloriosa Superb

In so limited a treatise it would be impos were it desirable, to mention all the features racteristics of the Jussieuian system, as comp in its ramified divisions, subdivisions, orders and species; and, indeed, to acquire any t useful knowledge on the subject, it must be practically in the garden and fields, under the tions of a master. It is generally allowed minute complexity of the subdivisions and most perplexing to the pupil, and a simplifi this respect, as well as in the harshness of the clature, would be very desirable. It is wel that there are many genera which stand on fines of two orders, with neither of which they agree. In such cases, uniting the neutral wi other of the more decidedly marked order surely be better than constituting a new order for the purpose of more completely or scie identifying one unsociable plant. It appears sieu himself was strongly impressed with the limiting the number of his orders, as well as the nevertheless, almost all the improvements wh been recently made in the system by his follo divisions of orders, and subdivisions of gen expanding rather than simplifying the system.

It cannot be denied, however, that there persons engaged in the cultivation of plants wi rejoice at seeing a new scheme of scientific which the orders of the natural system woul duced, and the number of genera diminished. thing is not so impracticable as may be ima master mind to contrive, and a few talented botanists to sanction the scheme, and fix the clature, would be a work well worth the atte labours of some universal botanical society for this special purpose.

Botany, as well as every other science, has la greatly advanced by that friendly and highly a able intercourse and interchange of social and communion between home and foreign pu and no doubt, whatever may be its defects, among its professors will speedily supply a re

ney round him; that the planets are globes similar to our own, revolving at once upon their own axis, and round the sun; that the moon is a satellite or attendant upon the earth, accompanying it in its course, and at the same time describing every month a circular orbit round it; and that to several of the planets are attached similar moons or satellites, bearing to them a corresponding relation.

By turning to our article ASTRONOMY, in which the number of the planets, and their distances from the sun, with other particulars, are noted, it will be seen that the earth which we inhabit is but a very small point, even in the solar system (as the concourse of planets round the sun has been called), and that it forms but a part of one magnificent and resplendant whole. But to ascertain the marks of a designing mind in this mighty maze of brilliant wonders, let us turn our attention to some of those particulars regarding them with which we are acquainted; and it must be confessed, that, if we are to suppose them mere masses of matter unclothed with aught bearing analogy to our vegetable productions, and uninhabited by beings either sentient or rational, it will be difficult to see why any of the arrangements connected with these bodies, so far at least as they themselves are concerned, and apart from their attractive influence upon our own world, should be either beneficial or the contrary. It is solely on the *conjecture* that there are organised beings on their surface to be warmed, and nourished, and upheld, that we can argue regarding such arrangements; and making this conjecture, we shall find that there are some very remarkable apparent contrivances for ministering to their comfort and happiness. It has been supposed that a planet so far distant as Herschel, or even Jupiter or Saturn, must suffer from an extreme deficiency both of light and heat; and hence it has been argued that they are necessarily unfit for the sustenance either of animal or of vegetable life. But when we consider that even Herschel, the most distant from the sun, possesses 248 times the light afforded by our full moon, it will not be difficult to believe, that, with a somewhat more acute power of vision than we possess, the inhabitants of that planet, if formed like ourselves, may be quite able to

IONS BETWEEN MAN AND EXTERNAL NATURE.

the evidences of design that are to be de-
m the contemplation of the heavens, let us
ne of the relations that exist between man
al nature, and consider the wonderful adap-
each other which they exhibit. There can
k in nature, and, consequently, no body is
all more or less influence each other, and it
of these relative influences that we are about
Man is attached by the laws of gravitation
th which he inhabits, and is surrounded by an
ic medium capable of exercising certain in-
pon him; these influences are modified by the
Power to be subservient to his wants, and
o be adapted not only to his necessities, but
every living thing, whether plant or animal,
s. The air which surrounds us exercises, in
ue of its extent, a pressure on the human
l to about 33,000 pounds. But why do we
and miserably perish beneath this immense
It is by the re-action of the elastic fluids con-
hin our bodies that we are enabled to support
us a pressure. Here we find a mutual rela-
ben us and the air, which cannot be inter-
thout mutual injury. Suppose this weight to
awn from our bodies, what would be the re-
e expansibility of the fluids contained within
have no restraint; they would dilate, burst
ie solids which contain them, and destroy the

mp, and withdraw the air, the result is very
One of the causes of the inconveniences that
lenced when on the summit of a very high
is, that the air is less dense, and does not op-
uch pressure to the body; and this it is which
the violent bleedings from the ears, eyes, and
at sometimes attack those so situated. The
cupping-glass, when applied to the skin, has
cause. We feel more or less the effects of
n change of atmospheric pressure, but still
y of the air is well adapted to the wants of
l it been greater, our energies would have
essed as by an unnatural load; and if less,
tly sustained as by a defective support. The
hearing and smelling, too, which depend for
ection on a medium density of the air, would
e either insupportably intense or defective.
ie atmospheric pressure materially affects
ire. If a certain quantity of air contains a
uantity of heat, it is clear that it must be
ffused throughout it; and if the same air be
in less bulk, or if the pressure be greater, the
ncreased in the same ratio. In the same
f the pressure be lessened, the air expands,
it the heat is diffused over a greater surface.
ressing air, we can produce a sufficient com-

degree. All organic bodies are capable of resisting to a great extent, and of modifying the action of, heat and cold; indeed, this principle of self-preservation is in them so striking as to have been regarded from a very early period as the most essential attribute of life. The power possessed by the higher classes of animals, of preserving a more or less uniform degree of heat, is almost unlimited. In very cold climates the thermometer not unfrequently sinks to 50° or 55° below the freezing point, while in very hot ones it is sometimes 120° or 125° above it, making a difference of 170° or 180°; still, however, the temperature of the body remains unchanged. What unanswerable evidence of design is this, and how limitless must be that Power who could create such wonderful adaptations!

If the atmospheric pressure produces in some measure the regulation of heat and cold, in no less degree does it affect moisture and its concomitants—clouds, mist, rain, snow, and hail; and thus we are dependent for many of our comforts, and for most of our necessities, upon the due adjustment of atmospheric influences. Winds, too, arise from any unwonted atmospheric pressure disturbing the equilibrium of the atmosphere, and are the efforts of nature to restore the balance. All the changes of weather, the most violent storms and tempests, own the same cause.

Connected with this subject, as evidencing design, is the composition of the air, which is precisely that best adapted to support respiration. It consists, besides small proportions of aqueous vapour and carbon, of two fluids, or gases, called oxygen and nitrogen. In a separate state these gases are inimical to life. Lavoisier proved by experiment that pure air, or oxygen gas, if respired for a certain time, rarifies the blood too much, and increases the rapidity of the circulation, the effects of which are violent fever, inflammation of the lungs, and death. Nitrogen is equally destructive to life, as not yielding that principle on which the purification of the blood depends. It is their combination that renders them salutary to the constitution, neither consuming life by too much stimulus and excitement, nor deadening its energies by a languid circulation and depression

matters are inherent in all living bo

ınd skill which its construction exhibits. At e time, it must be obvious that this construction 'ye would not answer its purposes, unless the tion of light corresponded to it. Light is an of the most peculiar kind and properties, and element can hardly be conceived to have been n the universe without some regard to its ope- and functions. As the eye is made for light, must have been made, at least among other r the eye. What we have said of light is equally)le to heat. It is obvious that the vital energy :s is much diminished, even suspended, during while with the return of summer they again 'rth their leaves and flowers; the same alterna- ains also among hybernating animals. Heat is ly the cause of these changes; so much so, in- ıat vegetables may be forced to invert the order easons. The climates in fact demonstrate the e of heat. How stunted is both animal and le life in polar regions, and how exuberant do ne individuals become under warmer skies! ity undoubtedly exists in the atmosphere in all es; but we know very imperfectly the laws of nt, and are still more ignorant of its atmospheric on. The present state of science, while it per- to hazard an opinion, does not enable us to e those adaptations of its laws to its uses, which discover in those cases where the laws and the e both of them more apparent. "It is at any rate obable," says Whewell, "that electricity has its ınt purposes in the economy of the atmosphere. is being so, we may see a use in the thunderstorm stroke of the lightning. These violent events th regard to the electricity of the atmosphere, rinds are with regard to heat and moisture. estore the equilibrium where it has been dis- and carry the fluid from places where it is nous, to others where it is deficient. We are tituted, however, that these crises impress every h a feeling of awe. The deep lowering of the f the thunder-cloud, the overwhelming burst of)losion, the flash from which the steadiest eye , and the irresistible arrow of the lightning which hly substance can withstand, speak of something even independently of the personal danger which ay whisper. They convey, far more than any)pearance does, the idea of a superior and mighty manifesting displeasure and threatening punish-

Yet we find that this is not the language which eak to the physical inquirer; he sees these for- symptoms only as the means or the consequences . In the world, these apparently destructive agents are, other movements and appearances of the atmo- parts of a great scheme, of which every disco- purpose is marked with beneficence as well as

think we have now sufficiently shown the won- ıdaptations and relations that exist between some phenomena of external nature and organised ces. It does not accord with our purpose to eeply or at greater length into the subject, but ıe little we have said, must, we hope, carry with)nviction, that verily it is a God who made and)e universe.

DESIGN IN THE STRUCTURE OF THE EARTH.

evident, even on a very casual inspection, that face or crust of the globe we inhabit has under- ıany changes, and these both great in extent and duration. Two agents, fire and water, have nainly instrumental in their production. The the great source of aqueous influence, seems, ime immemorial, to have been engaged in a e to degrade or level the surface of the earth, not only by the direct action of its tides and currents upon coasts, but also by means of the clouds of vapour which it sends up into the atmosphere, and which re-descend on the earth in the shape of rain and snow, giving rise to numberless springs and rivers, all of which have some effect, less or more, in washing down the dry land. This system of detrition, carried on from age to age, would have produced a state of things very different from that which now exists, had it not been for the antagonising agency of fire, which, working from the centre outwards, either by extensive convulsions or by slow upheavements, has elevated and repaired the earth's surface as fast as the waters have abraded it, and has compelled the ocean to give back to the light, in the form of continents and islands, the materials which it had before swallowed up.

In this reciprocal action and counteraction, and in their effects upon the earth's surface, we find abundant proofs of benevolent design. By these means have been produced those extensive irregularities—that diversity of hill and vale, ridge and plain—on which depends the fitness of the earth for the maintenance of all organic life, whether animal or vegetable. If the surface were level and smooth, the vapours raised from the sea by the sun would find no channel for their return, and the globe would necessarily become a stagnant marsh, unsuited for the residence of man and the greater part of the creatures that now tenant it along with him. But even if man could have inhabited the earth without its existing irregularities, how few comparatively would have been the advantages of his position! Had the matters carried down and deposited in the early seas, in the form of chalk-beds, limestone-beds, and coal-beds, with all the treasures of minerals and metals accompanying them, remained where they were first accumulated, man would have lost all the most essential elements of industry and civilisation. The changes and disruptions which have taken place in the crust, have brought to light a fund of riches, without which he would have been poor in comforts and in arts. Looking to those vast coal-fields alone, which the crust of our globe contains, can we imagine for a moment that the great changes by which these ruined forests of the primeval world were first spread out and moulded into new forms, and then upheaved to the reach of man, to supply him with endless stores of heat, light, and wealth, were produced by blind chance, or by aught but a creative designer, a being equally great and good!

On examining further into the condition of the earth's crust, as established by the changes it has undergone, we find numerous other proofs of the wise foresight which has ordered and arranged the whole. We discover that all the successive mutations of our planet, extensive as they have evidently been, were rendered compatible with the existence and enjoyment of countless numbers of organised and sentient beings. All the rocky strata of the crust, with the exception of those which appear to be the oldest and deepest-seated, are mixed up abundantly with organic remains, both animal and vegetable, and indeed some of the great limestone-beds are found to be entirely composed of the shells of insects. In short, whatever was the state of the surface at any given period of the revolutions fitting it for the ultimate residence of man, we find organised beings to have sprung up upon it, with such habits and peculiarities of structure as enabled them to exist and enjoy existence under the peculiar circumstances in which they were placed. Nothing can more distinctly show that our planetary revolutions had a noble scope and purpose, and were under the guidance of laws framed by a being as benevolent as wise.

DESIGN IN ANIMAL PHYSIOLOGY.

The earth, whose structure we have just briefly noticed, serves as the place of habitation for two kinds of existences—the animal and vegetable—in whose formation and functions we discover the beautiful dispensations of Providence, extending on every side over a vast range of beings, and demonstrating the unity of

plan on which organised creation has been devised. And, first, the whole circle of our knowledge does not afford greater evidence of design than comparative anatomy: in it we find innumerable contrivances for the comfort and happiness of the different tribes of beings adapted to the peculiarities of their condition; in each animal we see the same organ repeated, but modified to render it more available to the habits of its possessor; and among all the wonders of creation, there are none which strike the inquiring mind more forcibly than this change or modification of formation for the obvious purpose of accommodation to circumstances. Were all animals formed alike, or did the differences which exist between them bear no relation to their habits or destinies, it would be less easy to refute the doctrine which assigns all things to material causes, and excludes the designing hand of an intelligent Creator. Although even then the argument would be totally untenable, still the demonstration which disproves it would have been less satisfactory and perfect, as the surprising skill and beneficent care by which the structure of every animal is adapted to its individual habits and necessities, could not have been so well displayed. A single tool in the hands of the carpenter is a proof of contrivance, but that proof is much multiplied and rendered more forcible when we find the same instrument modified into a thousand forms to suit the different operations of the workman. Few of the functions of animated beings better illustrate this than that of alimentation, which we shall now briefly trace, through the humble zoophytes and worms up to birds and mammiferous animals. Nutrition is common to all animals without exception; and the numerous and varied modifications of the means employed to effect it, are obvious proofs of the design and intelligence of the Creator. There are some animals so nearly allied to plants as to be scarcely distinguishable from them; and in these, as in plants, nutritive matter is introduced by mere imbibition. Fixed like plants to the spot where they grow, any other organs would have been superfluous; while to those which are not so attached, but seek their food and obtain it through their locomotive powers, organs for seizing and preparing it are necessary. In them, therefore, we find lips variously and curiously modified; glands about the mouth for furnishing fluids for lubricating dry alimentary matters; a tongue, or something analogous to it; teeth and jaws for breaking down hard substances, and rendering them fit for swallowing; with a passage called the œsophagus, or gullet, leading from the mouth to the stomach, in which the food is at last assimilated, and rendered fit for nourishing the animal. But it is not until we advance some way in the great chain of animal life that these parts become sufficiently obvious, or their offices clearly defined. In the very lowest orders, the mouth and stomach are one continuous tube, or all stomach, as it may be called, and so simple in construction, that the animal may be turned inside out without detriment to it; that which was external being now internal, and performing, apparently with equal facility, all the offices of what was previously the stomach. As we advance, however, we find the nutritive organs ceasing to be a mere sucking apparatus, or a receptacle for imbibed fluids. In those whelks which are furnished with proboscides, we find a cavity occupied by the aperture of the œsophagus, a tongue, and teeth; while the snail possesses a perfectly formed mouth and lips. Among the worms, whose stomachs are generally membranous bags, we find examples of wonderful contrivance and design. Thus, the powerful stomach of one species contains three hard calcareous shells, by which the individual is enabled to bruise and masticate the shelled animals on which it feeds. The discoveries of Ehrenberg respecting the animalculæ inhabiting different vegetable infusions, have extended, in an extraordinary degree, our knowledge of the stupendous power of God; and the inimitable proofs of design displayed in beings to whom, in relative size, the mite is as an elephant, afford astonishing displays of a minute and most beneficent attention to the preservation of the creatures, in whose organisation and instinct admirable indications of creative wisdom are By the aid of the microscope, we are enabl ceive the Creator of the universe minutely t the worlds of living creatures to which he birth on a blade of grass, or in a drop of wa discover fresh scenes of wonder, and interes dent design, among hosts of animated beings, number as in minuteness. These discoveries an able analysis was lately given by Dr G the Edinburgh New Philosophical Journal, pated the obscurity in which the animals plunged, and displayed the wonders of their tion. To render their digestive organs mor cuous, he supplied them with coloured fo communicated its tinge to the cavities thro it passed. The moment a minute particle of attenuated solution of pure indigo was appli drop of water on the field of the microscope, were some of the infusory animalcules, the s tiful phenomena presented themselves. Pros bodies, which had been hitherto quite transp came dotted with a number of spots of a colour, evidently produced by particles of in mulated in these situations. In some species larly those which had a contracted part, between the head and the body, these particl be traced in a continuous line in their pro the mouth to these internal cavities. In this the employment of colouring matters, Ehren ceeded in ascertaining the existence of a sys gestive cavities in all the known species of th animals: one of the largest of which he fou sess a highly complicated structure with regu organs: with respect to the nutritive function a head provided with a regular apparatus for tion, consisting of jaws having from two to which were seen actively opening and shutt the animal was taking its food.

As we ascend higher in the scale of exis find the digestive apparatus ceasing to be a vities, or canals hollowed out of the substanc body, and becoming distinct organs formed branes and coats proper to each; and amon the first example occurs in the sea anemone, we find spaces intervening between the coat stomach and the skin of the animal: here, the stomach is still a blind pouch, one apertu ing alike for receiving and ejecting the ali matters. In the *echini* or sea-urchins these or still more perfect. Those of mastication are p developed; an œsophagus or gullet also presen and a stomach continued into a regular intestin takes two turns in the body before it terminat

DESIGN IN THE FORMATION OF INSECTS.

In the digestive organs of insects we mee multitude of new and peculiar formations, wh of the simple forms found in the lower animals repeated. The organs of mastication, deglutit suction, present such remarkable differences, arrangements of modern systems of entomol been chiefly founded on them. In this order of nutrition by vegetable substances is much more than in those below it; indeed, as Blumenbach served, the business of nutrition in insects does to have for its object the mere preservation o dividual, as in most red-blooded animals, but c consumption of organised matter, which will from considering the structure of their aliments In most of those which are subject to a metam the stomach in the larva state is of a great size parison with the short intestinal canal; while the contrary, which take little or no nourish their perfect state, have this organ remarka nished, and, as it were, contracted. How be does the great size and straight course of the apparatus of the animal, when in its caterp

ide with its enormous voracity and quick diges-

It has been computed that caterpillars some- devour and digest no less than three times their weight of aliment in four-and-twenty hours. On ther hand, during the subsequent metamorphosis the animal undergoes, no food is taken; but e, or rather the God of nature, has wonderfully, vith beneficent design, provided against any neces- or this, by causing insects to become very fat, as ved by Malpighi, on the approach of these changes; at this fat, being absorbed into the blood while are going on, serves all the purposes of a supply mentary matters from without. The insects now r consideration exhibit at different periods of their nce the greatest contrasts, not only in external , but also in their habits, instincts, and modes of stence. The larva, as we have seen, is remarkable a voracity, requiring large supplies of food, and uming enormous quantities of vegetable matter; erfect insect or butterfly, having attained its full nsions, is sufficiently supported by small quantities more nutritious food, consisting either of animal s or of the fluids prepared by flowers, which are ually of a saccharine quality, and contain nourish- t in a highly concentrated form. It is evident that ame apparatus which is necessary for the digestion he bulky food taken in during the former period, ld not be suited for the assimilation of that which is ived during the latter; and that, in order to accom- ate it to this altered condition of its function, con- able changes must be made in its structure. Who believe that these changes are made without wis- or persuade themselves that all this is to be brought t by causes divested of knowledge and understand-

Dr Roget, in his admirable Bridgewater Treatise, eautifully illustrated the subject, by very clear rrect drawings by Mr Newport, of the three diffe- tates of the entire alimentary canal of the privet moth (*Sphinx ligustri*): first, when a caterpillar; as a chrysalis; and, lastly, as the moth: and of taking our text from Roget, or rather from He- we shall endeavour to give some account. We been that in the caterpillar the stomach forms by ge most considerable portion of the alimentary bearing some resemblance in its structure and ity to the stomachs of certain worms. This is ed by a large but short and perfectly straight in- e. In the chrysalis, these organs have undergone derable modifications; the whole canal, but more ally the stomach, being contracted both in length idth: the shortening of the intestine not being rtionate to that of the whole body, obliges it to ded upon itself for a certain length. In the moth, ntraction of the stomach has proceeded much er, and an additional cavity, which may be con- d as a kind of craw, is developed; the small in- e takes a great many turns during its course, and ge pouch has been formed at the part where it the large intestine. "When we consider," say r and Spence, speaking of the phenomena which ve detailed, "the adaptation of all these changes m, the loss of old organs and the acquisition of nes, to the functions and mode of life of the l, we see evidently the all-powerful hand of that hty Being who erected the universe, upholding s providence, and the law that he has given to r creature, the system that he at first brought into nce."

insects, all parts concerned in digestion are in al smaller and less complicated in the carnivorous in the herbivorous tribes, apparently from the ers on which the former subsist being already alised, and requiring, therefore, less preparation e they are received into the blood; and it is no indication of design, to observe in them how rably parts are adapted to the animal necessities. , scorpions, spiders, millepedes, and others which for the most part on hard animal substances, are shed with jaws of a firm horny texture, in many cases very large, when compared with the size of the animal; dragon-flies and beetles, particularly the stag-beetle, are examples in which the jaws are very large and manifest, often possessing tooth-like edges; and these, too, feed on smaller insects than themselves. In another description, of which the bee, wasp, and ant, are examples, we find the animal deserting the coarser kinds of food, living chiefly on juices; and in them also we again find the same mode of taking in nourishment, as in the lowest stages of the animal kingdom, viz., by means of organs of suction, which here, however, are combined with organs for mastication. These organs of suction are still more developed in insects, such as gnats, house-flies, &c.; in them they consist of a tube, of which the sides are strong and fleshy, and moveable in every direction, like the trunk of an elephant, and having at its extremity a double fold, resembling lips which are well adapted for suction. The gnat, and other insects which pierce the skin of animals, have for this purpose instruments termed *lancets*, from their shape and office. In the gnat they are five or six in number, finer than a hair, exceedingly sharp, and generally barbed on one side; while in the house-fly they are flat, like the blade of a knife. In the butterflies, however, which are almost wholly independent of solid nutritive matter, these organs present themselves in the greatest perfection, and without any addition of teeth. The proboscis of this order of insects is a double tube, constructed by the two edges being rolled longitudinally till they meet in the middle of the lower surface, thus forming a tube on each side, but leaving also another tube, intermediate to the two lateral ones. This middle tube is formed by the junction of two grooves, which, by the aid of a curious apparatus of hooks, lock into each other, and can be either united into an air-tight canal, or be instantly separated at the pleasure of the animal.* It would be quite incompatible with the nature of this essay to enter at greater length into the evidences of design, deducible from the digestive apparatus of insects. "This immense class," says Cuvier, "in the structure of their alimentary canal, exhibit as many variations as those of all the vertebral animals together: there are not only the differences that strike us in going from family to family, and from species to species, but one and the same individual has often a canal quite different, according as we examine it in its larva or imago state;† and all these variations have relations very exact, often easily estimable, with the temporary or constant mode of life of the animals in which it is observable." That this statement is correct, we have seen; and no one can be blind enough to deny that it evinces an origin of things quite incompatible with mere brute and uncertain chance.

DESIGN IN THE FORMATION OF FISHES.

Still ascending in the scale of creation, we come to the contemplation of fishes. We ask, was it by mere chance that the respiratory apparatus of fishes was so formed that their blood receives its vivifying principle from the air which is held in solution by the water in which they move? And who cannot, in this one instance, but discern the hand of a ruling Providence, adapting the structure of animals to the habits which are to characterise them? Was it by chance that, in the plaice, the sole, the turbot, and other flat fishes, the eyes are placed both on one side of the body, an isolated instance of a want of uniformity in the two sides? No; the design is obvious: for as these animals are destined to continue always with one side in the mud at the bottom of the water, an eye on this side would have been superfluous and inconvenient to them. The same design and evident adaptation of structure to circumstances is apparent in the Surinam sprat. This singular animal generally swims so near the surface, that its eye is partly in and partly out of the water; and all its parts correspond with this strange peculiarity, the pupil being partially divided into an upper and a lower portion, and

* Roget, ii. 114.

† Imago or perfect state.

the lens consisting of two globes, an upper and a lower one attached together. It appears that the superior part of the eye is, like that of terrestrial animals, adapted to refract rays transmitted by air, and the inferior part, like that of aquatic animals, those transmitted by water, and that the refracting power of the several parts of the eye is accordingly much less above than below. With regard to the function of hearing, we find in fishes the Creator still proceeding on one vast plan or unity of design; with the exception of one species, all the parts of the ear are buried within the skull, and send no process to the surface; and this is precisely what we should have looked for in beings destined to hear through the medium of water, the vibrations of which being so much more powerful than those of air, would render the complicated apparatus requisite in terrestrial animals in them superfluous. In the class of fishes, we see the lowest condition of the alimentary canal as it is found in vertebral animals. Fishes, voracious to a proverb, subsist almost entirely on animal food. The ocean teems chiefly with animal life. It is a dense, and rich, and moving, and tempestuous element, where vegetation is comparatively small, contrasted with its developement in the light and unresisting element of the atmosphere. This rich and resisting element of water abounds in every latitude and in every drop, with all forms of animated beings. Thus, fishes have the means of easily satisfying their voracious appetites with a selection of all kinds of food. Their teeth, more instruments of prehension than mastication, are sharp, recurved, dense, and pointed cones, adapted to grasp and retain every living thing that moves in the waters, and placed in all parts of the mouth of these all-devouring animals; their œsophagus or gullet is very wide and short, and directly opening into their capacious stomach. Thus, the food of fishes not being masticated in the mouth, does not dwell there; and as they are surrounded with an abundance of moisture, they require no salivary glands for lubricating the food, and they have none. Like larvæ, their stomachs are very large; and like them, also, they are chiefly intent upon the gratification of their appetites. All other senses seem to be absorbed in this. Their brain is very small, and their senses correspondingly obtuse.* The intestine of fishes varies considerably in length, according to the kind of food; but, generally speaking, it is not longer than their bodies; whereas, in most reptiles —which compose the next class of animals in the ascending scale—it is considerably longer; a provision unnecessary in fishes, perhaps, from the matters on which they for the most part feed, being almost always of the same nature as their own bodies, and therefore requiring comparatively little preparation.

Relinquishing our plan of illustrating design by an account of the digestive apparatus, let us consider, in reptiles, the organs subservient to the function of respiration, which, though somewhat similar to the organs designed for that purpose in birds and mammiferous quadrupeds, differ from those in some remarkable particulars. In reptiles, indeed, as in birds and mammalia, there is a kind of lungs; but they are membranous and not fleshy; that is to say, the cells which they contain are so much larger as to give them a membranous and not a fleshy appearance; nay, in many reptiles the lungs consist of one membranous bag, very similar to the air-bladder of fishes. These lungs or bags are situated in the abdomen, and are loose and floating among the entrails; and they receive their supply of air, in general, not as in birds and mammiferous animals, in consequence of the formation of a vacuum around them, but by a process very similar to that of swallowing. Hence, reptiles, unlike the higher classes of animals, can still continue to breathe if their bodies are cut open, because they do not require a vacuum round the lungs. The air thus received is subservient to the purification of the blood in the usual manner; but it is not so immediately vivated as air received into fleshy lungs, owing t
size of the cells, which do not immediate

we know, is the warmest colour: and the pur-
ere is, to *keep in* the heat arising from the heart
rculation of the blood. It is further likewise
kable, that this is not found in larger birds; for
there is also a reason:—Small birds are much
xposed to the cold than large ones; forasmuch
y present, in proportion to their bulk, a much
surface to the air. If a turkey were divided into
ber of wrens (supposing the shape of the turkey
wren to be similar), the surface of all the wrens
exceed the surface of the turkey, in the propor-
the length and breadth (or of any homologous
f a turkey to that of a wren; which would be,
s, a proportion of ten to one. It was necessary,
ro, that small birds should be more warmly clad
rge ones; and this seems to be the expedient by
that exigency is provided for.
oil with which birds prune their feathers, and
gan which supplies it, is a specific provision for
ged creation. On each side of the rump of birds
rved a small nipple, yielding upon pressure a
-like substance, which the bird extracts by pinch-
pap with its bill. With this oil or ointment thus
red, the bird dresses its coat, and repeats the

haustless contrivances by which every difficulty is obviated, and nature moulded to the will of its Almighty Author. How many obstacles were to be overcome before a heavy body like that of an eagle or the mighty condor could be rendered buoyant in the air, and made to track its adventurous course so high above the earth as to be almost lost to human gaze! How many conditions were necessary to give safety and enjoyment to the smallest of the winged tribes, even after the first obstacles were overcome! Yet how wonderfully simple and efficacious the means by which the whole has been accomplished! That man is indeed to be pitied who can turn even a transient glance on such a subject, without being lost in astonishment and admiration.

THE STRUCTURE OF MAN AND OTHER ANIMALS.

We now arrive at the consideration of the mammalia, or those animals which suckle their young; and at the head of this great class we find man proudly pre-eminent. We have already seen, that, as the materials on which the function of digestion is to be performed are numerous and diversified, so a difference exists in the parts which are subservient to it. Without altering the general plan of the function, or the essential parts of the organs concerned in it, nature makes such additional provisions, in the instincts by which the reception of food is guided, and in the organs by which it is assimilated, as are suited to the circumstances in which the animal is placed, to the food on which it is to subsist, and to the ulterior purposes which it is to serve in the world. Such evidences of design are very remarkable in the mammalia; and in few organs are they more powerfully instanced than in the teeth, between which, in form, structure, and position, and the kind of food on which each animal of this class is intended to subsist, the most intimate connections present themselves. These relations—which indeed may be also traced in the shape of the jaw, in the mode of its articulation with the head, in the proportional size and distribution of the muscles which move the jaw, in the form of the head itself, in the length of the neck and its position on the trunk, and, in fact, in the whole conformation of the skeleton, have been noticed from very early ages

re is one circumstance connected with the function
estion, as displayed in certain of the mammalia,
ich, as evidencing great and wonderful design
commodation in structure to circumstance, we

particularly allude; it is the facility and power
camel of abstaining long from drinking—a power
he is often necessitated to bring into effect during
ng period of nine, ten, or even twelve days. In
a, the camel is the chief beast of burden; and
velling through such a country, it is only at
intervals that water can be obtained; a country,
cribed by Buffon, without verdure, without water,
ing a burning sun, an air always parched, sandy
, mountains still more scorched, which the eye
over without perceiving a single animated being;
d earth perpetually tossed with the winds, and
nting nothing but bones, scattered flints, rocks
ndicular or overturned; a desert totally void,
the traveller never breathes under a shade,
nothing accompanies him, nothing recalls the
f animated nature; absolute solitude, more dread-
an that of the deepest forests, more solitary and
, more lost in an unlimited void; he everywhere
ds space surrounding him as a tomb. The light
y, more dismal than the darkness of night, serves
o give him a clearer view of his own wretchedness

. Frightful as is this picture, the desire of lucre,
gratification of curiosity, and a love of enter-
no less insatiable, often tempt men to traverse the
y deserts of Arabia. For their own necessities they

provide, but no human means could afford the
bility of conveying water sufficient to satisfy the
ngs of the beasts of burden which accompany these
ditions. It is by the singular structure of the
l's stomach that it is enabled to pass several days
ut drinking, and to take at a time a prodigious
tity of water, which remains in reservoirs pure and
d, because these wells are so contrived that neither
uids of the body nor of digestion can mix with it.
t design is here!—and how redolent of wisdom,
ow full of mercy! But let us endeavour to explain

the nature of this structure which so evidently adapts the camel to be the inhabitant of the sterile and arid regions of the east:—Ruminating quadrupeds, or those which chew the cud, have two, three, or four stomachs, distinguished, when there are four, by the names of paunch, bonnet, many-plies, and caille. When the food is swallowed for the first time, it passes directly from the gullet into the paunch, where it undergoes some necessary changes, and it is then transmitted to the bonnet, to be mixed with the fluids of the cavity. This process is going on during the time the animal is grazing, when from the incessant occupation of nipping off the grass, for which its teeth are so admirably suited, it has not leisure to chew it sufficiently. When afterwards reposing itself, however, the half-chewed aliment is brought again in successive little balls, from the bonnet into the mouth, where it is subjected to a perfect mastication; and when again swallowed, it passes directly to the many-plies, thence, after some time, to the caille, and ultimately to the intestines. In the camel, however, the paunch has two deep cellular appendages; and the bonnet, or second stomach, has its internal membrane hollowed into numerous deep cells, serving as reservoirs of water, to be used only as occasion requires; while the third stomach is alone appropriated to the immediate necessities of the body. Between the end of the gullet, then, and the orifice of this third stomach, extends, through the two first, a long muscle capable of drawing up the third stomach, so as to receive alimentary matters directly from the gullet, when the immediate wants of the animal are to be supplied; but when the fluid taken is meant to be used only in its long journeys through the deserts, this muscle is relaxed, and it is thus received into the two first stomachs, and transmitted onwards by these only at the necessary intervals. The Arabs who traverse these extensive plains, accompanied by these useful animals, are, it is said, sometimes obliged, when faint and in danger of perishing from thirst, to kill one of their camels, for the sake of the water contained in these reservoirs, which is always found pure and wholesome. It is stated by those who have travelled in Egypt, that camels, when accustomed to go journies during which they are for a long time deprived of water, acquire the power of dilating the cells, so as to make them contain a more than ordinary quantity, as a supply for their journey.

COMPENSATION OF PARTS IN ANIMATED NATURE.

The evidences of design in creation are beautifully developed in what is called the compensatory structure of animals. By this is signified the supplying the defects of one organ by the structure of another part or organ. Paley has summed up a few striking instances of this nature. "The short unbending neck of the elephant (says he) is compensated by the length and flexibility of his *proboscis*. He could not have reached the ground without it; or, if it be supposed that he might have fed upon the fruit, leaves, or branches of trees, how was he to drink? Should it be asked, Why is the elephant's neck so short? it may be answered, that the weight of a head so heavy could not have been supported at the end of a longer lever. To a form, therefore, in some respects necessary, but in some respects also inadequate to the occasions of the animal, a supplement is added, which exactly makes up the deficiency under which he laboured.

If it be suggested that this proboscis may have been produced, in a long course of generations, by the constant endeavour of the elephant to thrust out his nose (which is the general hypothesis by which it has lately been attempted to account for the forms of animated nature), I would ask, How was the animal to subsist in the meantime, during the process, *until* this prolongation of snout were completed? What was to become of the individual whilst the species was perfecting?

Our business at present is simply to point out the relation which this organ bears to the peculiar figure of the animal to which it belongs. And herein all things

The hook in the wing of a *bat* is strictly a mechanical, and also a *compensating*, contrivance. At the angle of its wing there is a bent claw, exactly in the form of a hook, by which the bat attaches itself to the sides of rocks, caves, and buildings, laying hold of crevices, joinings, chinks, and roughnesses. It hooks itself by this claw; remains suspended by this hold; takes its flight from this position: which operations compensate for the decrepitude of its legs and feet. Without her hook, the bat would be the most helpless of all animals. She can neither run upon her feet, nor raise herself from the ground. These inabilities are made up to her by the contrivance in her wing; and in placing a claw on that part, the Creator has deviated from the analogy observed in winged animals. A singular defect required a singular substitute.

The *crane* kind are to live and seek their food amongst the waters, yet, having no web feet, are incapable of swimming. To make up for this deficiency, they are furnished with long legs for wading, or long bills for groping; or usually with both. This is *compensation*. But I think the true reflection upon the present instance is, how every part of nature is tenanted by appropriate inhabitants. Not only is the surface of deep waters peopled by numerous tribes of birds that swim, but marshes and shallow pools are furnished with hardly less numerous tribes of birds that wade.

The common *parrot* has, in the structure of its beak, both an inconveniency and a *compensation* for it. When I speak of an inconveniency, I have a view to a dilemma which frequently occurs in the works of nature, viz., that the peculiarity of structure by which an organ is made to answer one purpose, necessarily unfits it for some other purpose. This is the case before us. The upper bill of the parrot is so much hooked, and so much overlaps the lower, that if, as in other birds, the lower chap alone had motion, the bird could scarcely gape wide enough to receive its food; yet this hook and overlapping of the bill could not be spared, for it forms the very instrument by which the bird climbs; to say nothing of the use which it makes of it in breaking nuts and the hard substances upon which it feeds. How.

The Memoirs for the Natural His
published by the French Academy in

sed of such a property, it would inevitably die of
r.

carrying our observation upward from the mere
al organisation of man, to the *mind* which he
sses, and is able to exert in reference to both sen-
bjects and abstract subjects, we have still greater
n to admire the proofs of design and goodness in
erruling Creator; for we all feel that this principle
nd—how constituted we do not here stop to in-
—is in harmony with the other works of creation
ad us. For example, how much are our minds
l to the recognition of what is beautiful in nature
rt. This, however, admits of a few separate ob-
tions.

BEAUTY.

e wisdom of the great original Contriver is emi-
y manifested in that property of inanimate and
nte objects which we call beauty. Here there is
ident fitness between the taste and habits of ani-
human beings included, and what can be seen by
ye. We feel pleasure in contemplating the works
ture most obvious to our senses; and we cannot
emark, that that which is loathsome is not ordi-
presented to the eye. The splendid colouring
vegetable kingdom, the smooth or spotted skins
brute creation, and the lovely plumage of the
red tribe, all give us delight in the contemplation.
er, also, how beautiful is the outward appearance
human form. Reflect on what the parts and
ials are of which the fairest body is composed,
further observation will be necessary to show
ell these things are wrapped up, so as to form a
hich will be capable of symmetry in its propor-
nd of beauty in its aspect; how the bones are
d—the bowels concealed—the roughness of the
smoothed and softened; how over the whole is
an integument, the skin, which converts the
ing materials of a dissecting-room into an object
action to the sight, or one upon which it rests at
ith ease and satisfaction.

more minutely that we inspect the works of
, the greater cause have we to wonder at the
rdinary perfection and beauty every where pre-
The microscope developes splendours in the
creation of insects which we can hardly comprehend. The back of a diamond-beetle exhibits an assemblage of brilliant colours and glittering gems more splendid than any artificial arrangement of the most precious stones. The colours of the feathers of birds in tropical climates, and the skins of the fishes of Ceylon, are incomparable for their beauty. And why is all this the case? Because it yields a pleasure to the sight, both of men and other living creatures; for the Creator has not denied the feeling of delight to the meanest reptile which crawls. All is beautiful, it would appear, in the estimation of one or other of living creatures. The most insignificant little flower, now blooming far from the haunts of men, in some remote wilderness, does not, as has been said, waste its sweetness on the desert air. It furnishes an object of pleasing gratification to some description of sentient creatures, perhaps so small as to be imperceptible to our naked eye.

Placing agreeableness of aspect entirely out of the question, there is another purpose answered by the skin, and that is concealment. Were it possible to view through this integument the mechanism of our bodies, the sight would frighten as much as it would disgust us. Durst we make a single movement, or stir a step from the place we were in, if we saw our blood circulating, the tendons pulling, the lungs blowing, the humours filtrating, and all the incomprehensible assemblage of fibres, tubes, pumps, valves, currents, pivots, which sustain an existence at once so frail and so presumptuous?

In clothing the human frame with a covering of skin, the Creator has not omitted to vary its character according to local necessities. The skin is most beautiful on the face, because the face is most exposed to observation; it is softest where least liable to injury, and hardest or firmest in texture where it is most subject to be pressed upon. There is not less sign of contrivance in the manner in which it ceases at the extremities of the toes and fingers. A man has only to look at his hand, to observe with what nicety and precision that covering, which extends over every other part, is here superseded by a different substance and a different texture. Why do we find the skin cease at our fingers' ends, or on the back part of the fingers, and not the fore part? Because something hard or horny was required on these parts, by which we could hold fast or lift nimbly objects which we wished to grasp or seize upon. Nails therefore supersede the skin on such places. The same forethought is visible in the covering of our heads. What could have been a more beautiful or appropriate substance wherewith to cover the head and preserve the hard bony skull from injury, than the hair, a substance at once light, warm, and graceful?

DESIGN IN VEGETABLE PHYSIOLOGY.

In accordance with our intentions of glancing through most of the natural sciences, and bringing home to the main object of our labours treasures illustrative of design from them all, let us now turn our attention to those afforded by the vegetable kingdom of nature. And first, of the mutual relations that exist between animals and vegetables; in considering which, we shall find that these two great organised kingdoms of the creation are made to co-operate in the execution of the same design; each ministering to the other, and preserving that due balance in the constitution of the atmosphere, which adapts it to the welfare and activity of every order of beings, and which would soon be destroyed were the operations of any one of them to be suspended. "It is impossible to contemplate so special an adjustment of opposite effects, without admiring this beautiful dispensation of Providence, extending over so vast a scale of being, and demonstrating the unity of plan on which the whole system of organised creation has been devised." We said in a former part of this essay, that two principles of atmospheric air were oxygen and carbon; that the former was as essential to animal life as the latter was obnoxious to it; but that, on the other hand, carbon was indispensable to the continuance of

to expose a large surface to the contact of air. This object is accomplished by their division into numerous cells or leaf-like processes, or by their extension on the walls of cavities, or the surface of pectinated ridges. The blood brought to these organs is there distributed by their terminating branches. Although still retained in vessels, it can nevertheless be easily acted upon by the air on the exterior. Priestley found the colour of blood changed by the air when enclosed in a moistened bladder, and the same effect was observed by Hunter when it was covered with goldbeaters' skin. It is scarcely possible to determine by direct observation what is the exact nature of the changes that the blood undergoes in its passage through the lungs; the most obvious is its change of colour; and the chemical differences between the dark purple blood in the veins before it has reached the lungs, and the bright vermilion colour it exhibits in the arteries after it has circulated through the lungs, and been exposed to the influence of the air, may be collected from the changes made in the air itself. Atmospheric air is known to consist of certain principles in definite proportions; when it has acted upon the blood, and is returned from the lungs, it is found that a certain proportion of oxygen which it contained has disappeared, and that the place of this oxygen is almost wholly supplied by an addition of carbonic acid gas and watery vapour. The exact quantity of oxygen which is lost in natural respiration, varies in different animals, and even in different conditions of the same animal. Birds, for instance, consume larger quantities of oxygen by their respiration, and hence require, for the maintenance of life, a purer air than other vertebrated animals. Vauquelin, however, found that many species of insects and worms possess the power of abstracting oxygen from the atmosphere in a much greater degree than the larger animals; thus, snails are capable of living for a long time in the vitiated air in which a bird had perished. Some insects which conceal themselves in holes, or burrow under ground, have been known to deprive the air of every appreciable portion of its oxygen. It is observed by Spallanzani, that those animals whose modes of life oblige them to remain for a great length

sation; in the latter, it is that of exce
fluous quantity of carbon from the an

These it is true, do not visit the flower for the purpose ring the pollen; they only seek for the sweet ich exudes from its nectary. Their hairy body, ature did not bestow without design, is seen with pollen, often in such quantities as to im- progress of the animal; this, whenever they ther flower, is rubbed against the stigma; and ct, no less wonderful than calculated to fill us miration at the wise provision of nature, that sects are peculiar to one flower, and that others, ee, will only visit one species in each journey hive.

arious methods which nature employs to dis- e different varieties of seeds over the earth, y wonderful. Many plants, when the seed is e, discharge it from its covering, with a jerk or pring. The common oat is thrown out in this d the loud crackling of the pods of the broom sunshiny day, or, as Drummond has it, "burst- -balls crackling in the sun," is caused by their ; and scattering about the contained seeds, and ave been frequently noticed. "Who has not " again asks Sir James Edward Smith, "in a l sunny day, to the crackling of the furze bushes, by the explosion of their elastic little pods; or the down of innumerable seeds floating on a breeze, till they are overtaken by a shower, noistening their wings, stops their farther flight, the same time acccomplishes its final purpose, ediately promoting the germination of each seed moist earth! How little are children aware, ney blow away the seeds of the dandelion, or ars in sport upon each other's clothes, that they illing one of the great ends of nature!" These appendages to which Sir J. E. Smith alludes, the lighter seeds, as the thistles, and carry ating through the air to great distances. Then re the currents of rivers which bear the seeds ne part of the country to another; and even seas eans, whose tides and currents float along the of vegetation to the various regions of the globe. too, by feeding on particular seeds, carry them t distances, where, being often voided entire, egetate. There is evident design in this. It not have been by mere chance, that in flowers stand erect, the pistil is shorter than the stamens, ting the pollen as it falls to descend upon the ; and when the flower is drooping, that the con- rrangement is effected. And surely no one will d or hardy enough to assert that the mecha- eans, to which we have alluded, for the disper- seeds, with all the beauty and aptitude of its ement, was not the result of divine wisdom—a which will be still more apparent when we our views from the power which called into being arious and beauteous existences, and gave the of distributing them over the globe, and consider s that govern that distribution which we so much

not here out of place to remark, that there is y a vegetable production on which some species nal does not subsist; and, generally speaking, er that peculiar production is to be found, there the animal to which it furnishes wholesome food. some striking examples of this kind, the most ated man is acquainted; he knows that the par- is on the plain, the woodcock in the forests, the on the moors, and the ptarmigan on the loftiest of the mountains. He knows, too, that other migrate from country to country, seeking their distant regions, over trackless oceans, when it their native haunts; and among the animal m so universal is this, as to form an example of

the wonderful adaptations which exist between it and the vegetable world. Vegetables, like animals, are adapted to varieties of climate and temperature; and when we consider their distribution over the globe, we shall find that those which are most essential to the maintenance of man, bear a variety of climate better than most others. This is the case with greens, carrots, potatoes, and many kinds of grain. Warm climates are much more favourable to vegetation than cold. In Spitzbergen, the whole number of plants with conspicuous flowers, natives of the country, is found by botanists scarcely to exceed thirty species; while in the warmer regions of the West Indies, in Madagascar and the coast of Coromandel, Willdenow enumerates from four to five thousand different species of indigenous plants. Now, observe how admirably this distribution of plants corresponds with the wants and necessities of man. A vegetable diet is most suitable both to the tastes and the actual needs of the inhabitants of warm climates, and there we find that kind of food most abundant.

It is impossible for a reflecting individual to walk beside a field of growing barley, without being impressed with the conviction, that, in the economy of this description of grain, the design of a Creator has been wonderfully manifested. An ear of barley differs from one of wheat or oats. Each of the grains is furnished with a long slender bristle or beard, which is prickly to the touch, and seems to serve as a protection to the ear. These bristles form a roof, if we may so call it, to carry off the rain from the ear, and yet, by their elegant disposition, do not prevent the heat of the sun and the light from influencing the grain. And why should such be the case with barley, when the ears of wheat, oats, &c., do not possess any such protective process? Because barley is a grain easily injured by wet, which if not carried off, would cause the ear to sprout even while on the stalk, and consequently be entirely useless to man.

In speaking of the economy of vegetable life, it should not pass unnoticed that there is a remarkable instance of creative wisdom in the means which have been arranged for the growth of plants from putrescent matter. All kinds of vegetable and animal substances, when deprived of life, as well as excrementitious matter, have a tendency to decomposition—that is, to resolve themselves into those elementary gases of which they have been chiefly composed. This process of dissolution, as every one knows, produces a most disagreeable odour, which is often inimical to animal life. But this is not an evil; it displays a bountiful provision in nature; for it tells us, in a way not to be misunderstood, that the substance undergoing, or about to undergo, the putrifactive process, should be buried underground; and being there deposited, it immediately proceeds to supply its no longer useful gases to the infant plants and crops of grain which flourish on the surface. Thus do we see another striking evidence of the harmonious design which every where prevails between the animal and vegetable creation.

It has been said that a vegetable diet is preferred by the inhabitants of warm countries: to them sobriety is an easy virtue and a happy consequence of the climate. The people of northern regions, on the contrary, are voracious from instinct and necessity. They swallow enormous quantities of food, and prefer those substances which in digestion produce the most heat. Obliged to struggle incessantly against the action of cold, their life is but a continual act of resistance to external influences. Let us not reproach them with voracity, and their avidity for ardent spirits and fermented liquors. Those nations which inhabit the confines of the habitable world, in which man is scarcely able to withstand the severity of the climate, the inhabitants of Kamtschatka, the Samoiedes, &c., live on fish, that, in the heaps in which they are piled up, have already undergone a certain degree of putrifactive fermentation. In them there is a necessity for this inward excitement, which in our climate would be inevitably

attended with disease, and probably death. The abuse of spirituous liquors is fatal to the European transported to the burning climate of the West Indies. The Russian drinks spirituous liquors with a sort of impunity, and lives on to an advanced age, amidst excesses under which an inhabitant of the south of Europe would sink.

The influence of climate not only affects alike the regimen of man in health, but of man in sickness; and it has been justly observed of medicine, that it ought to vary according to the places in which it is practised. A few substances, for the most part obtained from the vegetable kingdom, sufficed to Hippocrates in the treatment of diseases; and physicians who practise in a climate such as Greece, may imitate the simplicity of the father of medicine. Opium, bark, wine, spirits, aromatics, and the most powerful cordials, are, on the other hand, the medicines suited to the inhabitants of the north; and thus we are enabled to use freely those medicines which elsewhere would be attended with the utmost danger.

We are now prepared to understand the beautiful and wonderful harmony that exists between the distribution of man and plants over the globe; and no one, we think, can deny their meed of praise and admiration for the care and beneficence which this universal adaptation exhibits.

The frigid zone contains but few species of plants, and the verdure of those countries which lie within the polar circle is confined chiefly to the hills having a southern aspect, and the trees are of very diminutive growth. Besides mosses and lichens, there exist ferns, creeping plants, and some shrubs yielding berries of an agreeable flavour. The arctic regions of Europe are peculiarly favoured; for in certain parts of Lapland there are fine forests, and even rye and leguminous plants are produced.

In the high latitudes of the northern temperate zone are the pine and the fir, which show their adaptation to a cold climate by retaining their verdure in the midst of the regions of winter. To these, as advancing southward, succeed the oak, the elm, the beech, the lime, and other forest-trees. Several fruit-trees, among which are the apple, the pear, the cherry, and the plum, grow better in the northern half of this zone; while to its more southern parts, especially, belong the more delicate fruits, such as the olive, the lemon, the orange, and the fig, and, among trees, the cedar, the cypress, and the cork.

The space comprised between the 30th and the 50th parallels of latitude may be considered as the country of the vine and the mulberry. Wheat extends as far north as the 60th degree; oats and barley a few degrees farther. In the southern parts of this zone, maize and rice are more commonly cultivated.

The vegetation of the torrid zone is characterised by a wealth, a variety, and a magnificence, which are nowhere to be found in the regions of the globe. Under the beams of a tropical sun, the most juicy fruits arrive at perfection; and innumerable productions supply the wants and administer to the luxuries of man. There the grounds yield the sugar-cane, the coffee-tree, the palm, the bread-tree, the pisang, the immense baobab, the date, the cocoa, the vanilla, the cinnamon, the nutmeg, the pepper, the camphor, and numerous other fruits and aromatics. In South America is the remarkable tree called the *cow-tree*, which, when incisions are made in its trunk, yields abundance of a glutinous and nourishing milk.

CONCLUSION.

But we must hasten to conclude our interesting subject. Illustrations of design might be produced from the works of nature without end; every link in the chain of creation teems with proofs of it; in none can any one affirm with truth that it is wanting. Cursory as our remarks have been, they still must lead to the general conclusion that not only design, but unity of design and identity of operation, pervade the works of nature, in as far as relates to organised existen
even among those portions of creation which are
nic, there do we find the same evident desire a
to render them subservient to the wants and n
of those which are. To several of these we hav
though it did not accord with our plan to allude t
we need only further draw attention to the re
uniformity in the plan of creation. The unive
is a system; each part depending upon other
being connected with other parts by some comm
motion, or by the presence of some common s

to strengthen that conviction, they have attain
object. We cannot close them more fitly, p
than by extracting a few lines from the powerf
ming-up by the poet Young, of the arguments
very subject.

"What am I? and from whence?—I nothing know
But that I am: and since I am, conclude
Something eternal: had there e'er been nought,
Nought still had been: eternal there must be.
But what eternal?—Why not human race?
And Adam's ancestors without an end?
That's hard to be conceiv'd. Yet grant it true,
Whence earth and these bright orbs?—Eternal too!
Grant matter was eternal, still these orbs
Would want some other father;—much design
Is seen in all their motions, all their makes:
Design implies intelligence, and art;
That can't be from themselves, or man: that art
Man scarce can comprehend, could man bestow?
Who motion, foreign to the smallest grain,
Shot through vast masses of enormous weight?
Who bade brute matter's restive lump assume
Such various forms, and gave it wings to fly?
Has matter innate motion? then each atom,
Asserting its indisputable right
To dance, would form an universe of dust:
Has matter none? Then whence these glorious for
And boundless flights, from shapeless, and repos'd
Has matter more than motion?—has it thought,
Judgment, and genius?—is it deeply learn'd
In mathematics? Has it fram'd such laws,
Which but to guess a Newton made immortal?—
If so, how each sage atom laughs at me,
Who think a clod inferior to a man!
If art to form, and counsel to conduct,
And that with greater far than human skill,
Resides not in each block—a Godhead reigns—
And if a God there is, that God how great!"

—an antiquity considerably greater than that of any profane history. At whatever time, however, the different books were written, they were not collected from the sacred depositories of the Jews, where they had been carefully placed, till long after their immediate authors were deceased; and their present arrangement, as we shall afterwards explain, is of comparatively modern date.

From an early period, it was the custom of the Jews to divide the books of the Old Testament into three classes, which they respectively designated the *Law*, the *Prophets*, and the *Hagiographa*, or *Holy Writings*, which last division includes more particularly the *poetical* parts; and some are of opinion that Jesus Christ alludes to this division of the scriptures, when he says that "all things must be fulfilled that were written in the *Law of Moses*, and in *the Prophets*, and in *the Psalms*, concerning him." For by the book of *Psalms* they understand all the books of the third class. *The Law* comprehends the *Pentateuch*, that is, Genesis, Exodus, Leviticus, Numbers, and Deuteronomy —such including both an historical narrative, and the injunctions forming the legal code of the Jews. The prophetical books are eight: namely, 1. *Joshua;* 2. *Judges*, with *Ruth;* 3. *Samuel;* 4. *Kings;* 5. *Isaiah;* 6. *Jeremiah;* 7. *Ezekiel;* and 8. *the twelve Lesser Prophets.* The first four books of this division are called *the Former Prophets*, and the last four *the Latter Prophets. The Hagiographa*, or *Holy Writings*, are nine; namely, 1. *Job;* 2. *the Psalms;* 3. *the Proverbs;* 4. *Ecclesiastes;* 5. *the Song of Songs;* 6. *Daniel;* 7. *Chronicles;* 8. *Ezra*, with *Nehemiah;* and 9. *Esther.*

According to the order in which the books of the Old Testament now stand, those of an historical nature are appropriately placed at the beginning. The first five books, having a chain of connexion throughout, are Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. These are styled the *Pentateuch*, such being the Greek compound for *five books.* They are likewise entitled the Books of Moses, from the belief that that enlightened Jewish leader composed them.

Book of Kings, or the *first of Samuel*, con-
tory of the high-priest Eli, of Samuel, and
of Saul; and extends over a period of nearly eighty years.

The *second* contains the reign of David, which is the history of about forty years. It is commonly believed that Samuel, Nathan, and Gad, were the writers of these two books; and indeed they are called, in the end of the first book of *Chronicles*, *David's historians*.

The *third*, or, according to the Hebrews, the *first Book of Kings*, begins with a relation of the manner in which Solomon came to the throne, and contains the whole of his reign. After that, an account follows of the division of the kingdom, and the history of four kings of Judah and eight kings of Israel. All these reigns, including that of Solomon, which occupies the first forty years, comprise the space of 126 years.

The *fourth* of these books contains the history of sixteen kings of Judah and twelve kings of Israel; and embraces a period of three hundred years. It likewise gives an account of the prophets who lived during this time. It is quite uncertain who were the writers of the two last-mentioned books. They are by some attributed to Jeremiah or Ezra, but no very convincing proofs have been adduced in support of this opinion. It is evident, indeed, that these books form a varied collection of several particular histories.

The name of *Paralipomena*, which, in Greek, signifies the *history of things omitted*, is given to the two books which follow those of *the Kings*. These form, in fact, a supplement, containing what had been omitted in the *Pentateuch*, and the books of *Joshua*, *Judges*, and *Kings*, or rather they contain a fuller description of some things which had been therein only briefly related. Some give them the name of *Chronicles*, because they are very exact in mentioning the time when every transaction happened. We divide them into two books, as do also the Jews, who call them *Dibere Hayamim*, that is, an *Historical Journal*, the matters of which they treat having been taken from the Journals of the Kings. In the original language, however, the word *days* often signifies *the year*, and in this sense we may understand the term to signify properly *Annals*. The generally received opinion is, that Ezra was the compiler of these. In the *first* book, he begins with a succinct historical abridgment, from the creation of Adam to the return of the Jews from their captivity; and then he resumes the history of David, and carries it on to the consecration of Solomon, that is, down to the year before Christ 1015. The history contained in the *second book* reaches down to the year before Christ 536, when, upon the expiration of the seventy years of the captivity, Cyrus gave the Jews leave to return to their own country.

Ezra wrote the history of the return of the Jews from the captivity of Babylon into Judea. It is the history of about eighty-two years, from the year of the world 3468, when Cyrus became master of the eastern empire, by the death of his father Cambyses in Persia, and his father-in-law Cyaxeres in Media, to the year 3550, which was the twentieth year of the reign of Artaxerxes, surnamed Longimanus. This book bears the name of Ezra, who was the writer of it.

The next book is a continuation of that of Ezra, and, therefore, it is by some called *the Second Book of Ezra*. It was Nehemiah, however, whose name it also bears, who wrote it, as is said, by the advice of Ezra. It contains the account of the re-establishment of Jerusalem, and of the Temple, and the worship of God. It is believed by some writers to be the history of about thirty-one years; but its chronology is exceedingly uncertain.

After this general history of the Jews, follow two histories of particular persons, namely, *Esther* and *Job*. The first contains the account of a miraculous deliverance of the Jews, which was accomplished by means of the heroine named Esther. The history of Job is not only a narration of his actions, but contains also the entire discourses which this pious man had with his wife and his friends, and is, indeed, one of the most eloquent and poetic books in the Holy Scriptures. It is uncertain who was the author.

Next to the *historical* books of Scripture, follow those of a moral nature. The first of these is the book of *Psalms*, which are likewise in some measure historical; for they recite the miracles which God had wrought, and contain, as it were, an abridgement of all that had been done for the Israelites, and that had happened to them. The Hebrews call them the *Book of Praises*, by which they mean, *of the praises of God*. The word *psalm* is Greek, and properly signifies the sound of a stringed instrument of music. The Hebrews sung the psalms with different instruments. We make but one book of them all, but the Hebrews divide them into five parts, which all end with the words *Amen, Amen*. Though the Psalms bear the name of David, yet they were not all composed by him: some of them are more ancient, and others are of a later date than his time; some of them being ascribed to Moses, Samuel, and Ezra. Speaking of the dedication of the second temple, Prideaux says, "In this dedication, the 146th, the 147th, and the 148th Psalms, seem to have been sung; for, in the Septuagint versions, they are styled the *Psalms of Haggai and Zechariah*, as if they had been composed by them for this occasion; and this, no doubt, was from some ancient tradition; but in the original Hebrew, these psalms have no such title prefixed to them, neither have they any other to contradict it." It is not probable, however, that all those whose names they bear were the true authors of them: it is more likely that these are only the names of those to whom they were first given to sing.

After the Psalms are the *Proverbs*, which are a collection of moral sentences, of which Solomon was the writer. This name is given them by the Greeks, but the Hebrews call them *Misle*, that is, *Parables*, or *Comparisons*; and the word may also signify *Sentences*, or *Maxims*. It is a collection of divine precepts, proper for every age and every condition of life.

The book which follows is also a *moral* one, and was likewise composed by Solomon. The Greeks call it *Ecclesiastes*, which answers to the name of *Koheleth*, which it bears in the Hebrew. Both these words signify, in our language, *a preacher*, or *one who speaks in an assembly*. In this book is given an admirable picture of the vanity of worldly expectations.

Among the *moral* books is also reckoned the *Song of Songs*; that is to say, according to the Hebrew manner of speaking, *a most excellent song*. It is an inspired production of Solomon, in the allegorical form of an *epithalamium*, or nuptial song significant of the marriage and fellowship between Christ and his people: "Its majestic style, its power on men's consciences to promote holiness and purity, the harmony of its language with that of Christ's parables, and of the book of Revelation; the sincerity of the bride in acknowledging her faults, and, in fine, its general reception by the Jewish and Christian church, sufficiently prove its authenticity."—*Brown*.

In regard to the Prophets, it may be observed, that all the Old Testament is considered to be in substance one continued prophecy of the coming of a Messiah; so that all the books of which it consists are understood to be in some sense *prophetical*. But this name is more especially given to those books which were written by persons who had a clearer knowledge of futurity, who forewarned both kings and people of what would happen to them, and who, at the same time, pointed out what the Messiah was to accomplish, whom they who are acknowledged to have been prophets had always in view; and this is what ought most especially to be taken notice of in their writings.

The Prophecies bear the names of those to whom they belong. Some learned men are of opinion that the Prophets made abridgements of the discourses which they had written, and fixed them up at the gates of the Temple, that all the people might read them; and that after this the ministers of the Temple might take them away, and place them among the archives, which is the reason why we have not the Prophecies in the order in which they were written. But the interpreters of Scripture have long since laboured to restore that c cording to the course of their history.

The works of the Prophets are divided into t the first of which contains *the Greater*, and th *the Lesser Prophets*. This distinction, of co not apply at all to the persons of the prophets, to the bulk of their works. *The Greater Pro* Isaiah, Ezekiel, Daniel, and Jeremiah. *The tions* of Jeremiah make a separate book by th containing that prophet's descriptions of the tion of the city of Jerusalem and of the captiv people. *The Lesser Prophets* are Hosea, Joe Obadiah, Jonah, Micah, Nahum, Habakkuk, Z Haggai, Zechariah, and Malachi. They were contained in one single volume, which the call *Thereaser*, which means *Twelve*, or *the Tw Twelve*.

The dates of many of the prophecies are u but the earliest of them was in the days of Uzz of Judah, and Jeroboam the Second, his contem King of Israel, about two hundred years b captivity, and not long after Joash had slain Z the son of Jehoiada, in the court of the temple. was the first of the writing prophets, and Joe and Obadiah, published their prophecies about time.

Isaiah began his remarkable prophecies a sh afterwards, but his book is placed first, becaus largest of them all, and is more explicit respec advent of Christ than any of the others. The h of this eminent writer is exceedingly sublime an ing; so much so, that it has never been equalled profane poet either in ancient or modern time impossible to read some of the chapters witho struck by the force of the prophetic allusions character and sufferings of the Messiah; and, sequence of these prevailing characteristics, the is ordinarily styled the *Evangelical Prophet*, some of the ancients, a *Fifth Evangelist*. Th say that the spirit of prophecy continued forty during the second Temple; and Malachi they Seal of Prophecy, because in him the succes series of prophets broke off, and came to a period book of Malachi, therefore, appropriately clo sacred record of the Old Testament.

By referring to our historical sketch of the people,* it will be observed that the glory of vanished at the period of the conquest and capti the nation, about six hundred years before Chri a consequence, though not an immediate one, spired writings of the Old Testament were cu soon after this event, or probably four hundred before the coming of the Messiah. Thus, a pe from four to five centuries elapsed from the time Malachi concluded his prophetic enunciations, t in which the Evangelists penned the books des of Christ's life and ministrations.

NEW TESTAMENT.

The second and lesser division of the Bible, been said, relates entirely to the Christian reli the fulfilment of that which was predicted and pre in the more ancient department of the work. division of the Sacred Scriptures is generally sty *New* Testament, or that which has been a later tion and bequest; that portion of it which re the history of the life of Christ is called the Gos by some the *Evangel*, both these words having th meaning, and implying *good news*, or *glad tidings* the circumstance that the narratives contain an a of things which are to benefit mankind.

The New Testament, like the Old, is a compila books written by different inspired individuals, put together in a manner so as to exhibit a t account of the birth, actions, and death of Chri doctrines he promulgated—and the prophecies r ing the future state of the church which he fo

* No. 6. in the present series.

historical books are the four *Gospels* and the *Acts* e *Apostles*, all these being of the character of nar- es of events; the doctrinal are the Epistles of Paul, some others; the prophetic book is the last, and is d the *Revelations* or *Apocalypse of St John*, hav- been written by that apostle while he was in the d of Patmos.

he four Evangelists, or writers, are Matthew, Mark, e, and John; these having, as is generally believed, companions of Christ during his ministrations, and efore personally acquainted with his life and cha- er. Each of the four books is principally a repe- n of the history of Christ, yet they all possess a rence of style, and each mentions some circum- ces omitted by the others, so that the whole is ntial in making up a complete life of the Messiah. e distinctions in the tone of the narratives, and r peculiarities, are always considered as strong cir- stantial evidence in proof of their authenticity, and here having been no collusion on the part of the ers. But, indeed, the events they record are de- d in so exceedingly simple and unaffected a man- that it is impossible to suppose that they were ten with a view to impose on the credulity of man- . The veracity and actual belief of the Evangelists selves are placed beyond a doubt.

he first book is written by Matthew, who was by a Jew, and exercised the profession of a publican at is, a collector of the public tax or assessment sed upon the Jewish people by their conquerors, Romans. Matthew, who was also called by the of Levi, was one of the twelve apostles of Christ, e is said to have written his narrative from thirty ty years after the departure of his Master from arth. Many of the ancients say that he wrote it Hebrew or Syriac language; but it is more pro- that there were two originals—one in Hebrew, he other in Greek, the former written A.D. 37 or nd the latter A.D. 61; and that these were respec- designed for the Hebrew and Gentile nations.

ith regard to Mark, the writer of the second Gos- t may be observed, that although Mark or Marcus common Roman name, there is reason to believe his Evangelist was a Jew, who had changed his nal appellation on being converted to the faith of st. Jerome says, that, after the writing of this el, he went into Egypt, and was the first that shed the Gospel at Alexandria, where he founded a ch, to which he offered an example of holy living.

e Gospel of St Mark is much shorter than that of hew, not giving so full an account of Christ's ser- as that did, but insisting chiefly on his miracles; n regard to these also, it is very much a repetition at we have in Matthew, many remarkable circum- es being added to the incidents there related, but any new matters. There is a tradition that it was written in Latin, because it was written at Rome; his is generally thought to be without foundation, that it was written in Greek, as was St Paul's le to the Romans, the Greek being the more uni- l language. The Gospel of Mark was written at newhat later period than that of Matthew.

uke, the name of the third Evangelist, is considered me to be a contraction of *Lucilius;* and he is said Jerome to have been born at Antioch. Some that he was the only one of all the penmen of the tures that was not of the Israelites; that he was a h proselyte, and was converted to Christianity by ministry of St Paul at Antioch; and that, after the g of Paul into Macedonia, Luke was his constant panion. He had employed himself in the study and tice of physic; and hence Paul calls him *Luke the ed Physician*. It is deemed probable that Luke e both his gospel and his narrative of the *Acts of postles* at Rome, when he was there a prisoner Paul, *preaching in his own hired house*—circum- es alluded to at the conclusion of the latter work. his be the case, Luke's Gospel may be dated about y years after Christ's departure, or A.D. 63. Jerome says that St Luke died when he was eighty-four years of age, and that he was never married. Dr Cave observes, that "his way and manner of writing are accurate and exact, his style polite and elegant, sublime and lofty, yet perspicuous; and that he expresses himself in a vein of purer Greek than is to be found in the other writers of this holy history." Thus he relates several things more copiously than the other Evangelists, and thus he especially treats of those things which relate to the priestly office of Christ.

The fourth Evangelist, John, was one of the sons of Zebedee, a fisherman of Galilee, the brother of James, one of the Twelve Apostles, and distinguished by the honourable appellation of *that disciple whom Jesus loved.* The ancients tell us that John lived longest of all the Apostles, and was the only one of them that died a natural death, all the rest suffering martyrdom. It is now established that he wrote his Gospel about the year 97 or 98, when he was of an extremely old age.

After the Gospel, or History of Jesus Christ, follows the history of what passed after his ascension and was transacted by the Apostles. The book, therefore, which contains this history, is called the *Acts of the Apostles.* It is a history of the rising church for about the space of thirty years. It was written, as has been already observed, by St Luke the Evangelist, when he was with St Paul at Rome, during his imprisonment there. In the end of the book he mentions particularly his being with Paul in his dangerous voyage to Rome, when he was carried thither a prisoner; and it is evident that he was with him when, from his prison there, Paul wrote his epistles to the Colossians and Philemon, for in both of these he is named by him.

Next to this come the *Epistles of St Paul,* which are fourteen in number; one to the Romans; two to the Corinthians; one to the Galatians; one to the Ephesians; one to the Philippians; one to the Colossians; two to the Thessalonians; two to Timothy; one to Titus; one to Philemon; and one to the Hebrews. They contain that part of ecclesiastical history which immediately follows after what is related in the Acts. The principal matter contained in them is the establishment or confirmation of the doctrine which Jesus Christ taught his disciples. According as the difficulties which raised disputes among the Christians, or the heresies which sprang up in the church from the first age of it, required, St Paul in these epistles clears up and proves all matters of faith, and gives excellent rules for morality. His epistles may be considered as a commentary on, or an interpretation of, the four books of the Gospel.

The Epistle to the *Romans* is placed first, not because of the priority of its date, but on account of its superlative excellence, it being one of the longest and fullest of all, and, perhaps, also, on account of the dignity of the place to which it is addressed. It is gathered from some passages in the epistle, that it was written in the year of Christ 56, from Corinth, while Paul made a short stay there in his way to Troas. He was then going up to Jerusalem, with the money that was given to the poor saints there; which is spoken of in the fifteenth chapter of the epistle.

The two Epistles to the *Corinthians* were written about a year after that to the Romans, viz. A.D. 57; that to the *Galatians,* A.D. 56; to the *Ephesians,* A.D. 61; to the *Philippians,* A.D. 62; to the *Colossians,* A.D. 62; two to the *Thessalonians,* A.D. 51 and 52; the first to *Timothy,* A.D. 64; the second to *Timothy,* A.D. 66; to *Titus,* A.D. 65; to *Philemon,* A.D. 62; and that to the *Hebrews,* A.D. 62. From which chronology it appears, that the Epistles of St Paul are placed in the New Testament rather according to the dignity of the cities to which they were sent, than according to the order of time in which they were written; for the Epistles to the Thessalonians were those he wrote first, though that to the Romans is placed before them. Interpreters are agreed that the last epistle which he wrote was the second to Timothy.

St Paul wrote to the churches of some particular places, or to some particular persons; but the other

however little they admit of controversy, it may, on the other hand, be observed, that the strong arguments and illustrations brought forward in the Epistles by Paul and others, were necessary, in order to combat the sophistry of the Greeks and the self-sufficient philosophies of other nations. Paul, the chief of the epistle writers, who became a Christian by conversion, after Christ had departed from the earth, is the great champion of the faith, and exposes, in strong and perspicuous language, the hidden depravities of the human heart; so that, where the affecting discourses and sufferings of the Messiah fail to convert and to convince, the reasoning of this great writer is calculated to silence and subdue those who stubbornly resist the benignant influence of the Christian faith.

Such, then, were the various books written to convey to posterity a faithful account of Christ's life and mission, and consequently of the religion which it was his purpose to institute. It will have been observed, that the whole were inscribed within the first century, and gradually accumulated in the hands of the primitive church, as an imperishable basis on which the faith of Christians should be founded.

AUTHENTICITY OF THE SCRIPTURES.—APOCRYPHA.

With respect to the authenticity of both the Old and New Testament books, as generally received, we of course look to the estimation in which they were respectively held by those with whom they had been deposited, and who unquestionably possessed the best evidences of their credibility. The Jews, as is well known, were most scrupulous in preserving entire the works of their inspired writers, and of preventing the intrusion of literal errors into the copies which were from time to time transcribed. Of the fidelity of the original text, there cannot, we think, be any reasonable doubt; and although there are what are called various readings, these are of an exceedingly unimportant character. Referring to this subject, it is said by the learned Dr Adam Clarke, "that all the omissions of the ancient manuscripts, put together, would not countenance the omission of any essential doctrine of the gospel, relative to faith or morals; and all the additions which then prevailed, and which they supp been traditionally conveyed down from writers.

The respect which the Jews have unifo the sacred books, has been almost allied to They are directed to be written upon pare from the skin of a clean animal, and to be with strings of similar substance, or sew hair which has been spun and prepared It must be likewise a Jew that writes t they are extremely diligent and exact i the least fault profanes the book. Every s ment is to contain a certain number of co are to be of a precise length and bre contain a certain number of words. Th written with the purest ink, and no word ten from memory; it must be first orall by the copyist. The name of God is d written with the utmost attention and c the transcriber is to wash his pen before it on the parchment. If there should el word with either a deficient or a redund should any of the prosaic part of the O be written as verse, or *vice versa*, the n vitiated. No Hebrew manuscript with an is, on any account, admitted into a synago private individuals are permitted to hav mented for their own use; but in the illu resemblance of any animal denounced by unclean cannot be admitted. of the sacred books as received by Protestants."—
nder's View of all Religions.

of that antiquity usually assigned to them, there cannot be any reasonable doubt; in other words, the writers wrote the books in perfect good faith, believing that what they penned was true, and the very books are those now before us in the New Testament. On these points, an able divine remarks:—"It must be esteemed a strong circumstance in favour of the antiquity of the New Testament, that on a subject in which the chances of detection are so numerous, and where we can scarcely advance a single step in the narrative without the possibility of betraying our time by some mistaken allusion, it stands distinguished from every later composition, in being able to bear the most minute and intimate comparison with the contemporary historians of that period. The argument derives great additional strength from viewing the New Testament, not as one single performance, but as a collection of several performances. It is the work of no less than eight different authors, who wrote without any appearance of concert, who published in different parts of the world, and whose writings possess every evidence, both internal and external, of being independent productions. Had only one author exhibited the same minute accuracy of allusion, it would have been esteemed a very strong evidence of his antiquity. But when we see so many authors, exhibiting such a well-sustained and almost unexpected accuracy through the whole of their varied and distinct narratives, it seems difficult to avoid the conclusion, that they were either the eye-witnesses of their own history, or lived about the period of its accomplishment."*

A minor point in the history of the Bible now requires to be noticed. In the earliest times the writings of the Old Testament were divided into books and short paragraphs equivalent to verses; but the division into chapters and verses in which they now appear was of a much later date. The separation of both the Old and New Testament books into chapters and verses, is by some writers ascribed to Arlott, a Tuscan monk, or rather to Hugh Cardinalis in the thirteenth century; while others allege that, from the comments of Theophylact on the Gospel, this must have been effected two centuries earlier. The question is not very important, and it is sufficient for the purposes of general knowledge

writings. With the earliest organisation of tian church may be said to have commence in the history of the Bible. The Old Testa whether in the form of Hebrew, Chaldai versions, were still cherished by the Heb hood as they are at this day; but copies w accessible to the early Christians, and by apostles and disciples they were treasured phetic testimony of God's eternal design fo tion of mankind, in the grand event whi actually occurred—the coming of Jesus Ch

When the books of the New Testamen lected and authenticated by the early fathe members of the Christian church, they w equal esteem with those of the Old, and ca served along with them. Though still manuscripts, they were generally in the Gr but, during the first three centuries of our or the language of the Romans, came larg in literature, and, in the same manner as European languages in later times sup Latin, so did the Latin supersede the Gre tine (born 354—died 430) mentions that, pr time, there existed a great number of La of the Scriptural writings. "We know translated the Scriptures into *Greek*," sa the number of them is not great; but th the *Latin* translators is infinite. When th to be established, the first man who fel copy, notwithstanding the little knowledge two languages, boldly undertook a transl From another passage of his writings it ha rally concluded that there was one partic called "the Italian," in higher estimati rest, and which was the authorised version churches. However this may be, it is cer Latin church required a version of the formed directly from the Hebrew, as all the lations in existence at that time had been the SEVENTY. seems to us the most proper place to notice—
ust be clear to every one's comprehension—that,
safe custody and verification of the Scriptures,
he period at which the New Testament books
ollected, we are indebted to the Church, or, to
more plainly, that series of ecclesiastical func-
es whose history is extended from the apostolic
till the present. Until the Bible, therefore, was
d to the people by the greatest of all mechanical
tions, the art of printing, and in that respect
beyond the reach of private interpolation or error,
ty, as a record, was dependent on the care and
n of the church, and for the faithful performance
important service, no one surely will refuse a
ed of thankfulness and praise. From motives no
conscientious, many who have now the Bible in
ands may consider the Church a valueless insti-
; but to this incorporation are they unquestionably
ed for preserving the Scriptures through ages of
ution and civil uproar. From the era of Augus-
d Jerome, when copies of the sacred books came
onsiderably greater request by the scattered
es of the Church, transcripts were effected by
and latterly by monks, with a diligence and ac-
which demand our utmost esteem and appro-
. In the cells of monasteries, surrounded by
of barbarous nobles and their serfs, learning
refuge from oppression; and there, in the darkest
of European history, were humble and pious
astics engaged, certainly from no worldly consi-
on, in penning copy after copy of the Sacred
gs, and bequeathing them as memorials of their
ry to future and more fortunate generations.

h before and after the application of printing to
ly copies of the Bible, translations, either direct
the original tongues or from the Greek versions,
effected by almost every people to whom Chris-
was introduced. Thus, copies of the Scriptures
bic, Persian, Sclavonic, and other tongues, were
ed. One of the most ancient of these is that
ated for the use of the Armenian Christians in the
r sixth century.* Portions of the Scriptures are
stood to have been translated into Anglo-Saxon,
e in the first British churches, as early as the sixth or seventh centuries; and the whole Bible was translated by Bede, an eminent Romish ecclesiastic, in the beginning of the eighth century. The first English Bible we read of was that translated by Wickliffe, one of the earliest English reformers, about the year 1360, but never printed. The part of the English Bible first printed was the New Testament, translated by William Tindal, assisted by Miles Coverdale; it was printed abroad in 1526, but, giving offence to the church, was bought up and burnt. "In 1532, Tindal and his associates finished the whole Bible except the Apocrypha, and printed it abroad: but while he was afterwards preparing for a second edition, he was taken up and burnt for heresy in Flanders. On Tindal's death, his work was carried on by Coverdale, and John Rogers, superintendant of an English church in Germany, and the first martyr in the reign of Queen Mary, who translated the Apocrypha, and revised Tindal's translation, comparing it with the Hebrew, Greek, Latin, and German, and adding prefaces and notes from Luther's Bible. He dedicated the whole to Henry VIII. in 1537, under the borrowed name of Thomas Matthews; whence this has been usually called *Matthews's Bible.* It was printed at Hamburgh, and licence obtained for publishing it in England by the favour of Archbishop Cranmer and the Bishops Latimer and Shaxton. The first Bible printed by authority in England, and publicly set up in churches, was the same Tindal's version, revised, compared with the Hebrew, and in many places amended, by Miles Coverdale, afterwards Bishop of Exeter, and examined after him by Archbishop Cranmer, who added a preface to it; whence this was called *Cranmer's Bible.* It was printed by Grafton, was of large size, and published in 1540; and, by a royal proclamation, every parish was obliged to set one of the copies in its church, under the penalty of forty shillings a-month; yet, two years after, the bishops obtained its suppression by the king. It was restored under Edward VI., suppressed again under Queen Mary, and restored again in the first year of Queen Elizabeth, and a new edition of it given in 1562. Some English exiles at Geneva in Queen Mary's reign, namely, Coverdale, Goodman, Gilbie, Sampson, Cole, Whittingham, and Knox, effected a new translation, printed there in 1560—the New Testament having been printed in 1557—hence called the *Geneva Bible;* containing the variations of readings, marginal annotations, &c., on account of which it was much valued by the Puritan party in that and the following reigns. Archbishop Parker resolved on a new translation for the public use of the church, and engaged the bishops and other learned men to take each a share or portion. These being afterwards joined together, and printed with short annotations in 1568, in large folio, made what was afterwards called the *Great English Bible,* and commonly, the *Bishop's Bible.* In 1589, it was also published in octavo, in a small but fine black letter: and here the chapters were divided into verses; but without any breaks for them, in which the method of the Geneva Bible was followed, which was the first English Bible where any distinction of verses was made. It was afterwards printed in large folio, with corrections, and several prolegomena, in 1572: this is called *Matthew Parker's Bible.* The initial letters of each translator's name were put at the end of his part. The archbishop oversaw, directed, examined, and finished the whole. This translation was used in the churches for forty years, though the Geneva Bible was more read in private houses, being printed above twenty times in as many years."

Various editions of the Bishop's Bible were printed at London in black letter at the beginning of the seventeenth century; but notwithstanding the care that had been expended on it, the version was not very correct, and its language was often far from elegant. To amend these deficiencies, and to obtain a really excellent version, James I. ordered an entirely new translation, which is that now in common use throughout Great Britain. To effect this very important undertaking, forty-seven distinguished scholars were appointed, and

'or the more commodious comparison of different versions, of them have been sometimes joined together. In his d Bible, Origen placed, in different columns, a Hebrew oth in Hebrew and in Greek characters, with six different rersions. Elias Hutter, a German, about the sixteenth ', published the New Testament in twelve languages, , in Greek, Hebrew, Syriac, Latin, Italian, Spanish, , German, Bohemian, English, Danish, Polish; and the ible in Hebrew, Chaldaic, Greek, Latin, German, and a 'ersion. But the most esteemed collections are those in he originals and ancient translations are conjoined, such omptutensian Bible, by Cardinal Ximenes, a Spaniard; g of Spain's Bible, directed by Montanus, &c.; the Paris y Michael Jay, a French gentleman, in ten large folio , copies of which were published in Holland, under the r sanction] of Pope Alexander VII.; and that of Brian afterwards Bishop of Chester. This last is the most ind valuable: it contains the Hebrew and Greek originals, ntanus's interlineary version; the Chaldee paraphrases, uagint, the Samaritan Pentateuch, the Syriac and Ara-s, the Persian Pentateuch and Gospels, the Ethiopic Song of Solomon, and New Testament, with their re-Latin translations; together with the Latin Vulgate, rge volume of various readings, to which is ordinarily astel's Heptaglot Lexicon—all included in eight volumes *Brown's Dictionary of the Bible.*

l scholars are now greatly assisted in their studies by ication of poly-glott editions of the Bible, containing in columns versions in various ancient and modern lan-The word *poly-glott* signifies many tongues.

writer, whether the translation was effected from Hebrew copies of the Old Testament or the Greek Septuagint, or whether any transcriptions of the original manuscripts were consulted;* but it is allowed by all persons competent to judge, that the version possesses extraordinary merit, and is the most perfect ever produced.

CHRISTIANITY.—HISTORY OF THE CHURCH.

Early History.

At the period of Christ's appearance on earth,† the land of Judea had sunk to the condition of a Roman province, and its people, the Jews, were in a condition not only of civil but great moral degradation. Their religion, as appears from all history, had degenerated from its ancient and lofty character, and existed only as a system of empty external observances in the hands of a priesthood to the last degree corrupt. The leaders of the people, and the chief priests, according to the account of Josephus, were persons of profligate manners, who had purchased their places by bribes or by acts of iniquity, and who maintained their authority, in subordination to the Roman civil power, by flagitious crimes. The multitude, affected by the example of their superiors, were not less corrupted in morals; and in a general sense it may be understood that the entire nation was in a state of lamentable disorder. To aggravate the distractions of the people, they were divided into a variety of sects, who, in proportion as they neglected the essentials of religious faith and practice, occupied themselves in disputes respecting matters of inferior concern. Of these sects, three in a great measure eclipsed the rest, both by the number of their adherents, and also by the weight and authority which they acquired: these were the Pharisees, the Sadducees, and the Essenes. The chief difference of opinion among these leading sects regarded the interpretation to be put on the *words* in the Holy Scriptures; and none of them seemed to have the interests of true piety at heart. The best of the three was the Essenes, who discountenanced ostentation in religious offices, and inclined to lives of secluded meditation. While the Jews, then, were thus broken up into contending sects, and were

The humble but intrepid apostles, the course of their preaching and teaching d afterwards in other countries, took no design to subvert temporal governments, them into contempt; neither did they themselves with civil rulers, but confined in all places to their proper functions of ers to be converted to the faith of Jesus, those who mourned, animating the piety ted, and, in particular, assisting the poor

Of the forms of Christian worship in state of the Church, little is known; and, pears that some time elapsed before the r at least the pupils to the apostolic teachers, forms enjoined in the old Judaic mode of cording to Mosheim, they "held separate n which they were instructed by the apostles prayed together, celebrated the holy supper ance of Christ, of his death and sufferings, ation offered to mankind through him; and usion of these meetings, they testified their , partly by their liberality to the poor, and ber and friendly repasts, which thence were *of charity*. Among the virtues which dishe rising church in this its infancy, that of to the poor and needy shone in the first h the brightest lustre. Having finished their rusalem, the apostles proceeded to other travelled over a great part of the known short time planting a vast number of nong the Gentiles. Several of these are n the sacred writings, particularly in the *Apostles*, though these are undoubtedly but of the churches which were founded, either les themselves or by their disciples under liate direction."

our design to enter into a formal detail of nted the various points of belief and relice in this early age of the Church. It will od that there was at first no body of written swering as a fountain of doctrine and preas we now possess in the collected books Testament; and that apostles, and those ised up to assist them in their holy cause, ingly thrown much more on their own resources, and more dependent on God's inspiring power to teach and direct, than required to be the case in more advanced times. To use the words of Mosheim—"Among the first professors of Christianity there were but few men of learning; few who had capacity enough to insinuate into the minds of a gross and ignorant multitude the knowledge of divine things. God, therefore, in his infinite wisdom, judged it necessary to raise up, in many churches, extraordinary teachers, who were to discourse in the public assemblies upon the various points of the Christian doctrine, and to treat with the people, in the name of God, as guided by his direction, and clothed with his authority. Such were the *prophets* of the New Testament."—(Rom. xiii. 6; 1st Cor. xii. 28; xiv. 3–29; and Eph. iv. 11.)

Much as we desire to do so, it is impossible for us to pass over a circumstance in the history of these early times, which has led to centuries of discord; we allude to the early form of church government. We shall allow a place to Mosheim's explanations on this subject. "Neither Christ himself, nor his holy apostles, have commanded any thing clearly or expressly concerning the external form of the Church, and the precise method according to which it should be governed. From this we may infer, that the regulation of this was, in some measure, to be accommodated to the time, and left to the wisdom and prudence of the chief rulers, both of the state and of the Church. If, however, it is true that the apostles acted by divine inspiration, and in conformity with the commands of their blessed Master (and this no Christian can call in question), then it follows, that that form of government which the primitive churches borrowed from that of Jerusalem, the first Christian assembly established by the apostles themselves, must be esteemed as of divine institution. But from this it would be wrong to conclude that such a form is immutable, and ought to be invariably observed; for this a great variety of events may render impossible. In those early times, every Christian church consisted of the *people*, their *leaders*, and the *ministers*, or *deacons;* and these, indeed, belong essentially to every religious society. The people were, undoubtedly, the first in authority; for the apostles showed, by their own example, that nothing of moment was to be carried on or determined without the consent of the assembly, and such a method of proceeding was both prudent and necessary in those critical times.

It was, therefore, the assembly of the people which chose their own rulers and teachers, or received them by a free and authoritative consent, when recommended by others. The same people rejected or confirmed by their suffrages the laws that were proposed by their rulers to the assembly, excommunicated profligate and unworthy members of the church, restored the penitent to their forfeited privileges, passed judgment upon the different subjects of controversy and dissension that arose in their community, examined and decided the disputes which happened between the elders and deacons, and, in a word, exercised all that authority which belongs to such as are invested with the sovereign power. The people, indeed, had in some measure purchased these privileges, by administering to the support of their rulers, ministers, and poor, and by offering large and generous contributions, when the safety or interests of the community rendered them necessary. In these supplies, each one bore a part proportioned to his circumstances, and the various gifts which were thus brought into the public assemblies were called *oblations*.

The rulers of the church were called either *presbyters* or *bishops*, which two titles are, in the New Testament, undoubtedly applied to the same order of men. These were persons of eminent gravity, and such as had distinguished themselves by their superior sanctity and merit. Their particular functions were not always the same; for while some of them confined their labours to the instruction of the people, others contributed in different ways to the edification of the church. Hence the distinction between *teaching* and *ruling presbyters*

*lopedia Americana, article CHRISTIANITY.

nor splendid. Three or four presbyters, men of remarkable piety and wisdom, ruled these small congregations in perfect harmony, nor did they stand in need of any president or superior to maintain concord and order where no dissensions were known. But the number of the presbyters and deacons increasing with that of the churches, and the sacred work of the ministry growing more painful and weighty by a number of additional duties, these new circumstances required new regulations. It was then judged necessary that one man of distinguished gravity and wisdom should preside in the council of presbyters, in order to distribute among his colleagues their several tasks, and to be a centre of union to the whole society. This person was at first styled the *angel* of the church to which he belonged, but was afterwards distinguished by the name of *bishop*, or inspector; a name borrowed from the Greek language, and expressing the principal part of the episcopal function, which was to inspect and superintend the affairs of the church. It is highly probable that the Church of Jerusalem, grown considerably numerous, and deprived of the ministry of the apostles, who were gone to instruct the other nations, was the first which chose a president or bishop. And it is no less probable that the other churches followed by degrees such a respectable example. * * * A bishop, during the first and second century, was a person who had the care of one Christian assembly, which at that time was, generally speaking, small enough to be contained in a private house. In this assembly he acted, not so much with the authority of a *master*, as with the zeal and diligence of a faithful *servant*. He instructed the people, performed the several parts of divine worship, attended the sick, and inquired into the circumstances and supplies of the poor. He charged, indeed, the presbyters with the performance of those duties and services which the multiplicity of his engagements rendered it impossible for him to fulfil; but had not the power to decide or enact any thing without the consent of the presbyters and people. And though the episcopal office was both laborious and singularly dangerous, yet its revenues were extremely small, since the church had no certain income, but depended on the

ORY OF GREECE AND ROME in the present series.

began to display a not less disgusting view of the persecution of Christians by the hand of Christians, carried on with a cruelty little short, in some instances, of that which Pagans had before exercised against them." *

To extinguish, as far as possible, the heresy of Arius, and allay other causes of schism, Constantine convoked the celebrated Council of Nice (325), which consisted of 318 bishops, and other ecclesiastics to the number of 2048. After a session of two months, in which the emperor frequently assisted in person, the opinions of Arius, which went to a denial of the divinity of Christ, were condemned, the equality of the three Persons of the Holy and Undivided Trinity was declared the true doctrine, and, being comprised in a form of belief called the Nicene Creed, was published as the obligatory and only orthodox creed of the Christian Church.†

The deliberations of the Council of Nice failed in their main design, and the Arians, persecuted by the Church, dispersed themselves in distant nations, and there found a safe retreat. This may be viewed as the first great schism in the Church, which henceforth consisted, not in one, but in several distinct societies of believers. To trace minutely the progress of the respective branching-off communions, would lead us considerably beyond our limits; let it suffice to say, that in the fourth and fifth centuries, there were founded several important eastern churches. The Armenian Church dates its commencement from about the year 312. The Egyptian or Coptic Church originated in a heresy in the fourth century; and the Abyssinian Church shortly after branched off from it. The Syrian Church, in a similar manner, gave origin to the Syro-Indian Church, which still exists in Travancore and Cochin, and acknowledges as its head the Patriarch of Antioch. It is likewise to the fourth century that we must trace the origin of that great schism which afterwards divided the Church into the Western or Roman Church, and the Eastern or Greek Church. At this period, the Bishop of Rome occupied the first rank in the episcopal order, and on that account exerted a certain authority over all other bishops within the pale of the orthodox Church. "Constantine, by removing the seat of empire to Byzantium (Constantinople), raised up in the bishop of this new metropolis a formidable rival to the Roman pontiff. Accordingly, in a council held at Constantinople, in the year 381, by the authority of Theodosius the Great, the bishop of that city was, during the absence of the Bishop of Alexandria, and against the consent of the Roman prelate, placed in the first rank after the Bishop of Rome, and

* Bigland's Letters on History.

† The Nicene Creed, after receiving some subsequent additions, stood as follows, and has for ages occupied a place in the Church service:—"I believe in one God, the Father Almighty, Maker of heaven and earth, and of all things visible and invisible; and in one Lord Jesus Christ, the only begotten Son of God, begotten of his Father before all worlds; God of God, Light of Light, Very God of Very God, being of one substance with the Father, by whom all things were made; who for us men, and for our salvation, came down from heaven, and was incarnate by the Holy Ghost of the Virgin Mary, and was made man, and was crucified also for us under Pontius Pilate: He suffered and was buried, and the third day he rose again according to the Scriptures, and ascended into heaven, and sitteth on the right hand of the Father, and he shall come again with glory to judge both the quick and the dead; whose kingdom shall have no end: And I believe in the Holy Ghost, the Lord and Giver of Life, who proceedeth from the Father and the Son, who with the Father and the Son together is worshipped and glorified, who spake by the Prophets: And I believe one Catholic and Apostolic church; I acknowledge one baptism for the remission of sins; and I look for the resurrection of the dead, and the life of the world to come. Amen."

With respect to the form of belief usually called the Apostles' Creed, it is believed to be of much less antiquity than the apostolic age, but there is great obscurity as to its authorship. It also has undergone alterations in the course of time. "The third creed, erroneously ascribed to Athanasius (who assisted at the Council of Nice in 325), is affirmed to have been privately drawn up about the middle of the fourth century; and is rejected by all the Protestant churches except the Anglican."—*Conder's View of all Religions.*

conferred on churchmen naturally introduced evils gross in their nature; and in many respects the alliance with the civil government did infinitely more harm than good. Some writers aver that Christianity could scarcely have survived the dismemberment of the Roman empire and the barbarism that ensued throughout the middle ages, unless fortified by civil power; but this, we humbly submit, is but a timid view of the Christian dispensation, which surely required no such extraneous means of support. It is a lamentable truth, confirmed by every respectable historian, that the proceedings of Constantine (321), and afterwards of Theodosius (390), in establishing Christianity as the religion of the empire, laid the foundation of every species of ecclesiastical abuse, and directly caused the decay of that sublime but simple piety which was the ornament of the apostolic times. It is to the arrangements consequent on the alliance of the Church with the civil power, that we have also to trace the origin of that new feature in ecclesiastical polity, the endowment of churches, cathedrals, abbeys, monasteries, and other institutions, with the functionaries belonging to them. But the most extraordinary change, both in the internal and external character of the Church, was the excess of power which, by the sanction of temporal princes, was accorded to the bishops of Rome. From early times, the occupant of the Roman primacy had been known under the title of *papas*, a Greek word signifying father, and hence the well-known terms, *papal* and *pope*. The pope, aided by his council, formed the head of the hierarchy, and acted as a supreme magistrate in all religious matters whatsoever. From the possession of the spiritual supremacy, a plea was easily found to assume the right of interfering in temporal concerns; and, as is known to the readers of history, the pope was allowed to exercise an almost unquestioned authority over the affairs of Christian princes for several centuries. It is at the same time proper to remark, that the lay and clerical members of the Church did not always agree in conceding this excessive power to the popes; the right of spiritual jurisdiction was not denied, but how far, and in what manner, that of a temporal nature, without the

The ludicrous extent to which the ex

om the pulpit he declared indulgences to be the most
lime of God's favours; they had saved more souls
n the efforts of all the Apostles; they would atone
every sin, however heinous; they were effectual in
ard to future, no less than past transgressions; they
ned for the dead no less than the living; and who-
r suffered his relatives to remain in purgatory,
en a little money would release them, was guilty of
worst crime. Hence a blow was struck at all re-
ıtance: contrition of heart was out of the question,
en pardon could be obtained on terms so much easier.
e present recital would perhaps be disbelieved, if its
th were not virtually admitted by contemporary
man Catholics. But good is often educed from evil;
l this preaching of indulgences was one of the chief
ses of the Reformation. There is reason to believe
t the whole system struck Luther with horror
m the very first; and that, coupled with the im-
ty which he had witnessed in the capital of Chris-
dom, it provoked his doubts as to the infallibility
the papal authority. The effects of the indulgences
re every day before his eyes; and, as one of the
thorised confessors of the people of Wittemberg, he
received them more clearly than other men. While
ted in the tribunal of penance, he was amazed to
ar what crimes had been committed, and still more,
t no contrition was felt for them. He refused to
olve, unless the criminals forsook their evil ways.
ey showed him their letters of impunity: no matter;
stimated these at their just value, namely, as so many
ces of waste paper. Being dismissed without abso-
on, and without admission to the sacraments, the
cled purchasers complained to Tetzel, who bellowed
threatened; but Luther was undaunted: he openly
ached against the pernicious traffic; he attacked
very foundation on which it rested; he denied the
er of pope or Church to remit the guilt of sin; and
is famous propositions, as every body knows, rapidly
duced the most gigantic change effected in this world
e the origin of Christianity." *

he preaching of Luther, in exposing the error of
ulgences, and calling in question various traditional
rts and practices, speedily roused a large part of
many; and as no symptom of relenting was shown
he part of those in power, an extensive secession
the Romish Church became unavoidable. The year
1 is to be regarded as the epoch of the Reformation
Germany; and from this period it became a political
well as religious movement—in a word, a movement
favour of civil and religious freedom. In conse-
nce of a general *protest* being signed by the reform-
party against a decree of the Diet of Spires, in 1529,
y received, in 1541, the name of *Protestants*. Eleven
rs earlier, in 1530, a declaration of the principles of
reformers, drawn up by Melancthon, was presented
he Emperor of Germany at a diet held at Augs-
g, and there solemnly read before the assembly;
famous declaration is known in history as the Con-
ion of Augsburg. The Reformation spread from
ntry to country with singular rapidity: the ancient
rch was deposed, and one of a reformed character
blished in its place—in Switzerland and Geneva in
5; in Sweden and Denmark in 1536; in England in
7; and in Scotland in 1560. In Austria, Italy,
m, Portugal, and France, the efforts of the reformers
e less successful, and in these countries the Roman
holic Church has been established, or at least popu-
till the present day.

CONCLUDING SUMMARY.

Christianity now exists, in one or other of its various
s, in all civilised countries, and numbers, as is
ed, 260,000,000, out of 900,000,000, the entire
lation of the globe. Although originating in Asia,
flourishing for some time in the adjacent regions
Northern Africa (Church of Alexandria, for example),
it prevails only to a small extent in these continents, and is principally confined to Europe and the countries which have been peopled by European emigrants. Every where, it is the religion of *civilised man*, no other creed or form of belief being at all suitable to an advanced intelligence, or so directly calculated to inspire sentiments of refined piety, humanity, and justice. In the hands of uninstructed, ambitious, and intolerant men, its history abounds in the most odious crimes; but latterly, as its professors have fallen under the influence of a civilisation to which it has itself largely contributed, and as the true principles of the Gospel have been better understood, our religion has not been outraged by indecent excesses either at home or abroad; while, by the earnest but unostentatious efforts of its supporters, of various denominations, it has been made favourably known in the most remote parts of the earth.

The forms in which Christianity is professed are very numerous, but the whole are comprehended in three leading systems—the Roman Catholic Church, the Eastern Churches, and the Protestant or Reformed Churches.* With a small exception, all acknowledge

* *Roman Catholic Church.*—The doctrines and ritual of this body, as now professed, proximately rest in a great measure on the decisions of the Council of Trent (terminated 1563). According to these decisions, the Romish creed embraces the following points:—An admission of apostolical and ecclesiastical traditions; that the Holy Scriptures form only a part of revelation, and are to be interpreted only according to the sense in which they are held by the Church; that there are seven sacraments, necessary for the salvation of mankind, though not for every one—baptism, confirmation, eucharist, penance, extreme unction, clerical orders, and matrimony; that in the mass there is offered a true, proper, and propitiatory sacrifice for the living and the dead; and that in the holy sacrament of the eucharist, there is really, truly, and substantially, the body and the blood, together with the soul and divinity, of Christ (transubstantiation); that there is a place of purgation, or purgatory, into which souls proceed after death; that the saints, reigning together with Christ, are to be honoured and invoked; that they offer prayers to God for us, and that their relics are to be had in veneration; that the images of Christ, of the Virgin Mary, and also of the other saints, ought to be had and retained, and that due honour and veneration are to be given to them; that the power of indulgences was left by Christ to the Church, and that the use of them is most wholesome to the Christian people; that the Holy Catholic Apostolic Church is the mother of all churches, and that out of the Catholic faith none can be saved. To these principal matters of belief are added—the efficacy of prayers for the dead; auricular confession; celibacy of the clergy; the use of Latin in the public ministrations; signing with the cross; the rosary as an implement of devotion, &c.

The Roman Catholic Church is an episcopacy, or government by a hierarchy of bishops. The supreme control rests in the pope and his council at Rome, and thence radiates a system of management, most complete and effective, over all parts of Christendom. The church includes three distinct orders of clergy—bishops, priests, and deacons; all others, such as cardinals (popes expectant), archbishops, deans, vicars, &c., belonging to one or other of these classes. The church claims the mark of true *apostolicity*, that is, an unbroken line of descent from the Apostles and their divine Master. The ordination of priests is the engrafting of them into this apostolic line of succession. Bishops alone ordain or communicate holy orders. In no church is the ritual of public worship so highly adorned, or rendered more imposing, by the dresses of the officiating priests, the waving of censers, crucifixes, pictures, images, and music. Although celebrated in an unknown tongue, it is observable that the public worship excites the greatest appearance of attention and decorum, as well as all the outward demonstrations of piety. The influencing of the devotional feelings is said to be the object aimed at by the various outward insignia; the church (if we understand the argument) holding it to be of equal consequence whether the heart is touched, and feelings of piety and veneration are excited, by the exhibition of a crucifix or the preaching of a sermon. The Roman Catholic Church, though now only a remnant of its former self, is still the most numerous of the various Christian bodies: it includes within its pale, France, Belgium, Poland, Italy, the Mediterranean islands, Spain, Portugal, the greater part of the people of Austria and Ireland; about a half of the Prussians and Swiss, and the

the doctrine of the Trinity, the fall of man, salvation by the expiatory death of Christ, the resurrection, and a state of final rewards and punishments. Differences on other matters may be traced to two distinct causes of controversy—1. Whether the rule of faith and practice is absolutely confined to the Holy Scriptures, or embraces a traditional revelation, sanctioned by councils and cherished by the Church? 2. And who has the right to interpret the rule of faith —the church or individuals? On the exact tion of these points, rests a complex series which at present appear to be as far from the mutual satisfaction of parties, as they sixteenth century; and we may rationally that, humanly speaking, little or no advance ciliation can be effected, till education has dispersed mists of prejudice, and enabled men to judge of abstract matters more equably.

inhabitants of various German states; large numbers in the South American states and Mexico; also a part of the population of the United States, and nearly all the Lower Canadians; and a considerable number of the inhabitants of England and Scotland, besides those of inferior countries. Altogether, the number of Roman Catholics is said to amount to 139,000,000.

The Eastern Church is divided into four leading communions, and several of a subordinate rank:—1. The Constantinopolitan or Orthodox Greek Church, comprising all who acknowledge the supremacy of the Patriarch of Constantinople. 2. The Russian Greek Church, which prevails over Russia, and in virtue of an ordinance of Peter the Great, in 1700, was constituted the national church, having for its head the Russian emperor; it is governed by a council at St Petersburg. 3. The Anti-Byzantine or Monophyte Churches, which have renounced communion both with the Constantinopolitan Church and Church of Rome, and differ from both in doctrine and ritual: these churches include the Syrian, Coptic, Abyssinian, Nestorian, Indo-Syrian, and Armenian Christians. 4. The Greek and other Eastern Churches, including the Maronites in Syria, who are in communion with the Church of Rome. The whole of these Eastern Churches are said to include 62,000,000 of members. Whatever be their peculiar differences, all recognise two sources of doctrine, the Holy Scriptures and Tradition, and are hierarchical episcopates in their form of government. The church service is in Greek. "The rites and ceremonies of the Greek Church are exceedingly numerous, trivial, and burdensome. In all the services, except the communion, prayers and adorations are offered to the Virgin (styled the *Panagia*, all-holy), or to some of the multitudinous saints of the Greek calendar, almost as often as to the Deity. Every day in the year is consecrated to some saint, frequently to more than one; and every day of the week is appropriated in the church service to some peculiar object of adoration."—*Conder*. This church does not resist the circulation of the Scriptures, and its clergy may be married men.

The Protestant Churches are either those which split off from the Church of Rome at the Reformation, or others which have since sprung from the reformed bodies. Protestantism owns two fundamental principles—that the Bible contains the sole rule of faith, and that it is the right of every one, without respect of person, to judge of that rule with all the aids which divine grace, reason, and conscience, can inspire. At the same time, it may be noticed, that in practice each church possesses certain standards of belief to which it is expected its members will adhere. Rejecting traditional revelation, and the decrees of all councils but those of an early date, Protestants admit only two sacraments, baptism and the Lord's supper. They reject transubstantiation and the sacrifice of the mass; deny the lawfulness of monastic vows, the holiness of celibacy, the merit of good works, the virtue of indulgences, the invocation of saints; reject the worship of Images, auricular confession, extreme unction, purgatory, prayers for the dead, and the spiritual authority of the pope. Protestantism exists in three main divisions—Lutherans, Arminians, and Calvinists—each differing from the other in certain points of faith and church government; but there are, besides, innumerable sects which cannot be included in these bodies—as, for example, Quakers, or the Society of Friends, who reject the lawfulness of clerical functionaries, and disapprove of the sacraments and all ordinary forms of public worship—Baptists, who also disown any clerical body, and agree in the necessity for adult baptism—Moravians, a large and unobtrusive body, who, among other good qualities, display extraordinary ardour in the prosecution of missionary labours—Methodists, a very numerous body, chiefly distinguished for the warmth of their piety, the reformation of manners, and the instruction of the young in religious duties by means of Sunday schools—and Unitarians, not a numerous body, who reject the doctrine of the Trinity; sometimes they are called Socinians, from the founders of their sect, Lelio Sozzini, an Italian nobleman who lived at the conclusion of the sixteenth century, and his nephew Faustus Socinus, who died in Poland in 1604. The total number of Protestants of all churches and sects is believed to be about 60,000,000.

Protestantism is professed in two chief forms—Episcopacy, or the government of the church by bishops, whose spiritual authority is derived from the apostles through the efficacy of both before and since the Reformation; and *Presb* rejects a hierarchy of bishops, and admits only the of the church by a body of ministers all equal in rank called *Independents*, or Congregationalists, only church being governed by its own members, on a pr simple model. At the head of the Protestant Episcop may be placed the Church of England, whose doctri tained in the well-known Thirty-Nine Articles and of Common Prayer. The Church of England has denial of the supremacy of the bishop of Rome, and doctrine of purgatory, the doctrines concerning indul pardons, the worship or veneration of images and re vocation of saints, the sacraments of confirmation, orders, matrimony, and extreme unction, transubstanti the sacrifice of the mass. It retains confirmation as ceremonial, ordination to the priestly office, the sign in baptism, burial service, kneeling at the communion, of the sick, the whole hierarchical routine of offices priests, deacons, prebends, archdeacons, rectors, vicar numerous fasts and festivals. In its calendar affixed of Common Prayer, there are retained the names of saints of the middle ages, such as Hilary, Prisc Dunstan, &c. Practically, the church pays no attenti or to most of the authorised fasts, festivals, rigils, &c ing to law, the reigning sovereign, whether a king head of the church, and has the appointment of its bi hold the dignity of spiritual peers, and are members lature. From its strict connexion with the state, the England labours under the misfortune of possessing itself to amend its formularies, which consequently they were in the reign of Edward VI.; yet this great tage is felt to be comparatively unimportant, on acc extraordinary beauty and simplicity of the language of and litanies, as well as the elementary nature of the vi which admits of no alteration by officiating ministers. a number of its clergy have manifested a strong desire many forgotten ante-Reformation usages in the church a circumstance which has given much offence to thos rate views. Both in the United States of America a land there are Episcopal communions deriving orders the Church of England, and having the same forms The Scotch Episcopal communion, in which the bish as ministers of congregations, and which is altogether on the contributions of its adherents, is acknowledged the purest model of the Episcopacy which prevailed ages of the Church.

Presbyterianism is established in Scotland, Holland, of the Swiss Cantons, and exists to a large exten America. Presbyterians generally follow the doctrin Calvin, rejecting the use of crucifixes, the sign of the liturgies, &c., and recognising no saints' days. Chr Easter are recognised by Presbyterians in Holland, those in Scotland. The clergy, being equal in ra verned by provincial and general courts, constituted own body. Scotland possesses a numerous body of P dissenters or seceders from the establishment; and these have added to former causes of difference, by their hostility to all connexion between Church and that Christianity, as was the case prior to the stantine, should be entirely independent of civil p and its ministers supported exclusively by voluntar tions.

ES OF LIFE.

tibility of human nature; but we understand this,
f human nature can be made to know wherein its
est good consists, it may be presumed that this
will be sought and obtained. Man was created on
rinciple, he acts on this principle, although he is
o frequently to make the most deplorable and dis-
ng mistakes. If it be not admitted that mankind
lways strive to obtain whatsoever seems to them
and strive to avoid whatsoever seems to them evil,
moral teaching is in vain. If this principle be
tal, the sole inquiry is—what is good? and what
?

INFANCY.

ry human being comes into the world with phy-
and intellectual qualities, propensities, and apti-
, which distinguish him as much from all other
, as he differs from them in figure and appear-
As society is a consequence of the Creator's will,
proper divisions of labour are a necessary con-
ce of society, it is not irrational to suppose that
iduals are born with adaptation to labour in some
ments, and not in others. In the early stages of
hese qualities are sometimes developed, whether
happen to be understood or not. But almost im-
ely after gaining some hold on life, all human
become subject to the incidents which tend to
hen original qualities, or to obscure or stop their
ss, and even to suppress them, and engraft on
riginal stock those which are entirely different.
uld be unjust to make infancy responsible for the
nd errors which arise in this manner; but cer-
those who have the guidance of infancy are re-
ible, and will be held to be so. Children have a
to complain, and society has a right to complain,
ies to children be neglected; and, it is needless
nark, there is another and inevitable accountabi-
a far more serious character. We shall have
on to remark on the very sober duties of those,
according to the order of natural and necessary
re intrusted with forming and giving effect to
l qualities. This matter properly belongs to
r place.

YOUTH.

come now to a period when accountability begins,
the relations which were placed in the division of
. If it be asked at what age this is to be fixed,
swer, that the good sense of judicial law recog-
that a child may be a witness in solemn judicial
edings, when inquiries addressed to him are so
ted as to make it certain that he understands the
e and the obligation of an oath. This may be at
s of ten or twelve years. But the perception of
and wrong, and the sense of duty, begin at an
r age. There certainly are children of the age

of eight years who have a very clear sense of moral propriety; and very many who, between that age and twelve, can discern and reason on right and wrong, and arrive at a very sound judgment. We shall presume that all into whose hands this sheet may fall, will be fully capable of comprehending its purpose, and of judging of its fitness to be useful to them. We must assume, then, that we are speaking to those who are willing to be instructed in serious things, and that they will not reject instruction from any source, however unpretending it may be, if it come to them in a manner which they can reconcile with their own reason, and with their own duty to themselves. Young persons think that they can see for themselves, and that they need not to be told what others have seen. But let us reduce this to common sense. Suppose a person to be under the necessity of going from the place in which he has lived, and which is familiar to him, to a far distant place. Let it be supposed that the road he must travel is crossed by many roads, and that he is frequently to find himself at points where several roads are seen, either one of which, so far as he can discern, may be the right one. Will it be of use to him to have been told, before he departs, which of these many roads to take? Will it help him onward to his destination, when he is bewildered, and unable to decide for himself, to find some one who can assure him of the right course? Life is a journey. Every step we take in it brings us to something new, something unexpected, and perhaps entirely different from that which was looked for. Those who have gone through it before us, have left us their instructions in what manner it is to be undertaken and accomplished. They tell us of their own troubles and difficulties; they warn us how to avoid the like in our own journey. Which is wisest—to listen to them, and weigh the worth of their warning, or to push on heedlessly, and take the consequences?

HEALTH.

We suppose that every child of the ages last spoken of, can form some opinion of the value of health. Most of them have suffered, more or less, by that time. They are now old enough to consider the purposes for which life has been given to them. They then feel that the purpose is to be pleased and gratified; to want and to have; and that restraint is disagreeable. But let them remember that life is a whole; that though all of them will not, yet some of them will, attain to its longest duration, and that it is wholly uncertain to whom that lot will fall. Long life may depend, and often does depend, on what children do, or omit, at an early age. Among the first gratifications which are looked for at this period, is the indulgence of the appetite for food. Here comes in a rigid law of the Creator. It cannot be broken without consequent suffering, nor repeatedly broken without impairing, and perhaps destroying, the material frame which has been described as so fearfully and wonderfully made. To require of that delicate machinery, on which the action of life depends, that which it is not qualified to do, and which it cannot do—to force it to do that which is offensive to it—and to make this requisition habitually—is a sin against natural law. Its punishments are well known. The restless sleep, the heavy head, the many sensations of uneasiness, the positive pain, the disgusting remedies, are the punishments which follow. They are not all. Nature loses its charms, companions their interest, duties become irksome, the mind hates its labour, penalties are incurred, parents or teachers are regarded with displeasure. These are the fruits of momentary gratification of the appetites. On the other hand, there is a law of nature that food shall be grateful. It is required to supply the daily waste—to continue life. If there were not a craving want, we should take food as a mere necessary duty. It is kindly made to be a pleasure, and, like every other pleasure, it is to be used, and not abused. Thus, by ignorant or wilful pursuit of pleasure, we violate a law which brings with its just punishment not only the loss of the like pleasure for a time to come, but also pain and suffering from indi[gestion] remedies. When children are sick, they are [objects] of tenderness and pity; but in most instan[ces] rather deserve to be punished, for they have [broken] a law wilfully, since they have disregarded [the] experience. As to kinds of food, nature is a[lso] sonably nice about this: that which it comp[rehends] quantity.

CLEANLINESS.

This is not a mere matter of decency. It [is] the positive commands arising from the [whole] order of things. Be it remembered, that ev[ery] that lives, vegetable or animal, is wasting whi[le it] tinues; and that all which is sent forth thr[ough] millions of openings by the skin, has run its r[ound] is lifeless; and that more than half of all the f[luid] comes forth in this manner. If perspiration, [which] and insensible, be permitted to rest on the [body] stop the way of that which is coming, nature is [at] and will show that she is so. Such neglect is o[ne of] causes of disease. This fact was probably w[ell] to eastern nations, since it was part of their [religious] duty to cleanse the skin. These nations were [the] of the modern comfort of wearing a garment [next] skin which can be frequently changed. The [use] of this comfort was one of the causes of those [loathsome] diseases of which we read, and which are now [unknown] among Christian nations. There are classes of [men] and mechanics, whose health would be preser[ved] their lives prolonged, if they knew how much [depends] on periodical cleansing. It may be said that [there is] a connexion between cleanliness and moral [purity]. Perhaps it may be going too far to say, that th[ose who] habitually disregard cleanliness, and prefer to [be] have no moral perception; but it may be truly s[aid] those who are morally sensitive are the more [scrupulous] respecting this virtue. There is a close affi[nity] tween moral depravity and physical degradation. [The] vicious poor are always shockingly filthy: the de[bauched] rich are visited by worse penalties: they ma[y have] clean garments; but what can wash away the [stains] ties which vice has made part of themselves? [Not] for one's self only that the virtue of cleanlin[ess] mends itself. Every one comes within the obse[rvation] of others. However uncleanly one may be him[self] is not the less offended at the like neglect in thos[e] he observes. Now, it is every one's duty to hi[mself] recommend himself to others, so far as he ina[smuch] and reasonably can, and to obtain their respect. [Rich] and costly garments may fall very short of dis[guising] if it be seen that they are a covering for the v[iolation] this important law. If there be a lovely objec[t] human eye, it is a clean, clear-faced, healthy, [and] neatly-clad, happy child. There are few child[ren] may not, if they will, be neatly dressed, for th[is] not depend on that of which the dress is made. [There] are fewer who may not have a clear skin, and [a] look, if they are properly fed, and sleep in p[ure] There are none who may not have a clean skin. [I] speak to those who are old enough to judge fo[r] selves. And let it be added, for their inducem[ent] in obeying the command to be clean, they are p[er]ing a moral duty; in neglecting it, they are inf[lict]evil on themselves in two ways—first, in dim[inish] their own comfort; second, in losing the es[teem] others.

AIR.

Among the generally unknown causes of loss o[f] is the respiration of impure air. The congre[gation] many persons in one apartment, especially wh[en] ficial light, in great quantity, is permitted, is a [fruitful] more maladies than is commonly supposed. [Various] causes, in such case, combine to destroy the f[itness] the air for respiration—the animal heat of the [body], the lights, and the breathing of the same air a[gain] again. There must be such assemblies. The [remedy] is proper ventilation. The smoke of lamps

h belongs to it, and that also which belonged
r and in another season of life.

SELF-LOVE.

n invariable law of nature, that every human
all do those acts which he thinks will secure
him, and that he shall avoid those acts which
ason evil to him. Why, then, should not every
any and every act in his power by which his
l may be gratified, and avoid doing any and
et which is disagreeable to him? The only
that can be given to this question is, that man
agent, intrusted with the power, and charged
duty, of ascertaining for himself what is good
t is evil; and that this power and duty extend
with whom he dwells in society, and also to his

ren always conform to the natural impulse of
, until they learn from the discipline which is
to them, that they cannot have their own will
subjecting themselves to a suffering, the dread
controls the natural impulse. They learn, after
that the greater good lies in giving up what
ll to do, and doing what is required of them,
than to meet the certain consequences. We
at the whole science of morals will be found in
ciples contained in the truth above stated.
ove is just as strong throughout life as it is in
od. It is that quality of our nature to which
dience may be referred; but it is also that to
ll unworthiness may be referred. As the dread
shment, or an unwillingness to displease those
kindness a child desires, will restrain him, or
into action; so, in more advanced life, the dread
ring a certain or probable evil, and the certainty

s founded in a submission to the Creator's laws.
goes on in life, he may or may not acquire more
re clear and just perceptions of what will be the
t good to himself, and how he can obtain it. It
f-evident proposition, that if a person could ex-
know what it would be best for him to do, or ask
in relation to all things and persons, and under
rcumstances, and if he should conform to thi

knowledge, he would best obey the impulse of self-love, and most exactly conform to the laws prescribed for his good.

It cannot be too often impressed upon the youthful mind, that *life is to be taken as a whole:* for if this extended view be not taken, it must frequently happen that it will seem right in certain circumstances, and when the view is limited to these circumstances, that certain acts may be done or avoided as the greatest good. Yet, if the consequences could be foreseen, they would disclose that this seeming good would turn out to be a positive evil. It often seems good to the young to avoid the performance of labours which are assigned to them, and to spend in amusement the time which should be devoted to fit them for duties which will be incident to their future condition. This misapprehension of good is to be lamented; but with some this is not all. Their own self-love prompts them to engage in a course of folly, so that not only do they fail to obtain that which is real good, but they find, under the mask of pleasure, that which proves to them to be the most grievous suffering.

The same truth runs, in an endless variety of forms, into manhood, and through all the stages of life. We are impelled by self-love not only to provide for the craving wants of our nature, but to seek pleasure, riches, power, distinction, and luxuries. These propensities are given for wise and beneficent purposes. It is the misapplication of them, as seen in the world, which constitutes human misery. He is called brave and honourable who defends himself, even at the risk of life, against those who would do to him that injustice and wrong which would make the gift of life of no value. But the brave, who invade the rights of others, and subject them, by violence, to losses and to sufferings, without cause, misapply this principle of action. To get riches by honest industry, or the reasonable exercise of one's talents, is a commendable use of self-love. To get riches by unfair and dishonest means, to hoard them up, and to brood over them in secret, is a pitiful misuse of this commendable impulse. To have power over one's fellow-men, and to use it faithfully, and for their benefit, is a relation which one may honestly and commendably desire, as a reasonable exercise of self-love. To seek such power by deceitful representations, and to obtain it by violence and fraud, and to use it for purposes of supposed self-benefit, and to the injury and oppression of others, is another form of self-love. But there are few, if any cases, in the history of mankind, in which self-love has appeared in the latter form, without eventually overwhelming the agent with disappointment and sorrow. It is true that for a time such an one may seem to flourish in his schemes, and command the applauses of those who look up to him in his apparently fortunate elevation; but, in the very nature of things, if his heart could be sounded, there is no one whom he looks down upon, who is not more at ease than himself. His day of humiliation may be at hand, in the course of events which he cannot control; and if not, he learns, when it is too late to correct his error, that he has misapplied the impulse of self-love. This misapplication is to be seen in many cases of daily occurrence, and in things of little, as well as in those of comparatively great, importance. The principle is every where the same.

We shall be answered, perhaps, that all this is incident to human nature. There is no help, it is said, for these evils. Every boy who has learned Latin repeats the maxim, *Humanum est errare* (It is human to err). A more mischievous maxim was never invented. If men understood, as most certainly they may do, that they need not err, and that it is best for them they should not, they would rather adopt as a maxim that none but the wilfully ignorant, and the wilfully foolish, *err*. Such a state of things is yet afar off. It may *seem* to be foolish, indeed, to assert that any society *should* ever come to be so well informed as to make a *proper* use of self-love. Let us not despair. We may *improve* very slowly; yet, if every one does even the little that he can, in showing, by precept and what things a rational and accountable desire, and what he should avoid and reject, the time may come when self-love will misapplied as to be necessarily followed by and sorrow.

Will it be denied that there is a certain of action for every human being, in every dition in which he may find himself? Or, the proportion of human suffering arises from discerned that it was best, in past circum have acted differently, or not to have acted that whether one did or did not act, in the case, that his motive was to secure to h greatest good of which that case was suppose If these things cannot be denied, then the g life is so to regulate self-love as that it may greatest good. Let us suppose that every society knew what it would be best for him to to do, so that his physical, intellectual, and dition, should be as good as he could make it love would never be directed to any end wh impair his bodily powers, or keep his mind in or misinformed, or make him a subject of re contempt in his own view, or in that of othe it will be said, is an impossible state of thi was said that it would be impossible to root o of *ardent spirits*. This great change is not complished; but does any one doubt that gre has been made towards its entire abolition! on, then, in the work of improvement. Let try to show the proper uses of self-love. Th come when every one will admit that all the which may visit the human family are of making, those only excepted which arise from ral laws of the Creator. As to those, they greatly mitigated by intelligent moral agency these come, they can and will be endured and resignation, if the sufferer can console him the certainty that he has done no wrong neglected any proper one, to which the suffer sufferings may be referred.

LABOUR.

It is commonly considered that labour is declared to mankind, as a consequence of the sion of the *first man*. It is foreign to our pu enter into any discussion as to the true meanin historical or allegorical account; the Christia tion may not be dependent on a literal under of it. However this may be regarded under the of further reasonable research, we must take he is; and so considering him, labour is not a *pleasure*. Is it a curse to man, as he now enabled *by labour* to comprehend the existen Deity, and the beauty and utility of his works! the earth and bring its productive power int to apply the material substances of the earth able use, convenience, and ornament! to ex improve the human mind! to cultivate and s the moral power? Certainly these are the labour; and labour so applied constitutes man happiness.

There are two kinds of labour:—1. Me labour; 2. Labour of the mind. These two times necessarily combined. The mind and demand some sort of employment. No one w is free from natural defect can prevent its a will think of something, good or evil, profitable Every one who attends to the operations o mind, must be convinced that this is so. The limbs cannot be kept in any one position for siderable space of time, unless they have been and demand repose. If it were painful to u the action of the mind to useful labour, and distressing or inconvenient to us to exercise cles for purposes which we believe to be prop might be that labour is a curse; but many who require of the mind to perform its duti

ose, and especially those who have disci-
ıind to an accustomed service, find that the
:mployment is an affliction. We cannot see
ɔuld be otherwise, if we rightly comprehend

:e be a doubt that, in man's present condi-
ɔility to labour is his exalted privilege? And
ccountable for this privilege? Is not reason
rect him in the use of it? It is well known
ıo have compared the condition of mankind
t ages, how much the labour of body and
been able to accomplish. Even within the
entury, the most surprising changes for the
e taken place, from the right use of this pro-
wer. On this depends the condition of the
ıily. From the joint labours of all who wish
ir fellow-men, there will be obtained, eventu-

ally, the knowledge of the best manner of using the products of the earth, the best mode of ruling men in their social relations, the just homage due to the Creator, and the true purpose for which human life has been given.

To some descriptions of persons, labour is irksome. They are obliged, in their vocations, to use certain muscles, and those only. They repeat the same act throughout the day. Their labour becomes tedious, because it requires little or no action of the mind. To this numerous class we venture to offer a relief which is within the easy reach of many of them. It is well known that the nature of habit is such, that the hands will do what they have been accustomed to do, without any obvious attention, and the mind is left to do what it will. The mind might be employed, while the hands are busy, in pursuing some connected train of thought. Muscular action, so far from being an interruption to the action of the mind, may be made to assist it. Persons who think intently are often seen to have some habitual movement; and we have heard several persons acknowledge that their best ideas had come to them when they were engaged in some simple occasional duty, such as the folding of paper, or the cutting of the leaves of a book. The stir of body seems to produce a corresponding stir of mind. The relief which we suggest is, that sedentary labourers should provide themselves with subjects for reflection, and exact of their minds to attend to these subjects. By such simple means, the memory may be strengthened, the stock of knowledge may be greatly increased, and the mind surprisingly invigorated. One might begin this exercise by attempting to remember, with the utmost precision, every act done during the preceding day, and so go back from day to day. Better still would it be, if the purpose were to see wherein one had not done as well as he might, and as he may wish he had done. This exercise may be applied, also, to the contemplation of subjects suggested by reading; and this contemplation will raise questions which will lead to the examination of books. There may be hundreds of poets, philosophers, and moralists, at the work-benches in this country, who have no thought, of themselves, that they are such. It is in the power of any person who can read and understand the English language, to strengthen his memory, give himself an interesting employment, and furnish himself with a rich fund of the truest philosophy, in this manner. He may commit to memory six lines, each successive day, of Pope's Essay on Man, and on each day repeat all he had learned on preceding days. On the 218th day he would be able to repeat the whole essay. This might be done without losing one moment of time, and without making the slightest error in one's work. When accomplished, it would be an intellectual treasure for which any man might be thankful, and of which he might be justly proud. The first efforts may be discouraging, but perseverance will ensure success. Every one who is accustomed to thinking can attest that most new subjects are at first confused and undefined; but they gradually disclose themselves, and fall into shape and order, just as material substances, used on the work-bench and the anvil, take that form, smoothness, and polish, by successive operations, which the workman requires.

HABIT.

This quality of our nature has engaged the attention of many philosophic minds. It has been considered an *ultimate fact*, as it is called; that is, one of those qualities, which, like respiration, digestion, and many others, are found to exist; and beyond which fact no investigation can be made. Its laws, rather than its nature, have been the subject of remark. It may be, that habit is to be referred to the law of action, which appears to pervade all material and intellectual being. Life is divided into parts; in one we are awake, and active; in the other, wrapped in sleep, and quiet. Each successive day is a sort of new existence, in which we are to repeat many of the acts of the preceding day. We

cannot go, that those acts are most easily and well done which are oftenest done. One who uses a flail, an axe, a scythe, a sword, or a pen, can use either the better the oftener it is used, until he arrives at a point of excellence at which his power of improvement stops. This may perhaps be accounted for by supposing that the first effort which the mind makes to direct muscular action, is the most difficult one. After repeated efforts, the mind seems to understand better and better how to direct, and the muscles how to obey, till at length a very slight effort of the mind seems to be all that is required, and even an effort so inconsiderable and rapid as not to be the subject of notice. On this truth seems to depend the astonishing facility of action to which (among many other instances) jugglers and musicians attain. This is called *habit*, which word is derived from a Latin word which signifies custom or use. There are customs or habits of the mind as well as of the muscles. Persons who accustom themselves to extemporaneous speaking, acquire a surprising ease and readiness in the complicated action of conceiving, uttering, and expressing, by sounds, by looks, and gestures, whatsoever they would impress upon an audience. The mind has its own habits also, in the quiet of contemplation, and in exercising its various powers. It has its own associations, too, with external objects, of which many curious instances are stated in philosophical works.

The moral deduction which we make from these general principles is this, that there is a continual craving to do some act, to obtain some object; or a continually recurring necessity to do some act, to prevent an evil or inconvenience. The frequency of this call upon us to do something, whether it be for eventual good or evil, leads to the practice, custom, or habit of doing; and in some cases the impulse to act becomes so powerful, that reason, self-respect, the laws of society, and even those of the Lawgiver of the universe (if these are heeded), present no sufficient barrier to the impulse. It is to this all-important truth in the nature of man, that we earnestly invite the attention of the young. The capacity to create habits is the consequence of the power given to us to promote our own welfare, indivi-

and character, from abusing the pr
nourishment, is universally condemn
motive, and the acts done in obedien
are irrational and disgraceful.

There are two kinds of intemperan
the young should be warned. The on
for nourishment, but for pleasure; th
tobacco. It has been already demonst

OF LIFE.

Will not the seeds you are now sowing come up
spans of time? Will they come up in the form
ebled muscles, chronic aches, self-reproaching
s, the loss of the capacity to enjoy the bounties
nties of creation? Will they grow up to over-
your moral sense, and shut out the delights of
tual power? Was life given to you for the few
which you can sing, drink, and "enjoy yourself,"
you may enjoy life in every stage of it, as a
l being, and by rendering your homage to nature
ing her laws, and your gratitude to Him who
d these laws for your happiness? Do you not
reward yourself to be at some time a parent?
our own parents ever so conducted themselves
you, that you have a right to punish and afflict
Are you willing that your parents should see
know you as you know yourself? If you should
rent, are you willing that your children should
with whom, and in what manner, you "enjoy
f?" Would you tell them how you spent your
l days and nights, and recommend to them to
urself as an example?

TRUTH AND FALSEHOOD.

e two subjects relate to two parties; 1. That
n speaks truth or falsehood; 2. That one to
it is spoken. We propose to consider this
nly in relation to the first party, and as to him
views. 1. Whether there be any, and what
ich requires that the truth should be spoken;
What good or evil one may do to himself by

ne reason why truth should be spoken is, that
owledge which any one person can have from
of his own senses, in many things which it
aterially concerns him to know, is very limited.
st therefore often depend for his knowledge on
thers say to him; and when the thing spoken
xclusively known to the party speaking, the
ust rely entirely on what he says. If, there-
be considered how great a part of the most
concerns in life proceed on declarations made by
son to another, we may readily conceive, that,
could not be relied on, the affairs of mankind
e greatly embarrassed, and confidence in each
ould be destroyed. As this matter of speaking
th is one which concerns all persons, so all per-
gree in holding liars in contempt. Even the
west persons consider themselves to be disgraced
harged with the guilt of lying. They can endure
which would subject them to public punishment,
ore composure than they can endure this. A lie
ys understood to be resorted to to secure some
ge or prevent some evil to the person who
to it; or to occasion some disadvantage or
to the person to whom, or of whom, the lie is
ometimes both these purposes concur. The
n view is always an immoral one, and the means
e always regarded as disgraceful. It is at once
that wilful falsehood is forbidden by natural
hich is intended to regulate our social relations,
expressly forbidden by divine law, which con-
all acts of fraud and deceit, and commands us
others as we would have them to do to us.
is a rare occurrence that any one who descends
hood succeeds in the object which he may have
. He is commonly detected, and, if not, is sus-
which may operate quite as much to his disad-
. If he should escape detection and suspicion, he
constant fear of both. He has a very troublesome
to keep. If he should be able to do this, still he
hide it from himself that he is a liar; and such
n, by natural justice, is compelled to pass that
e upon himself, which he knows that others
pass upon him if they were as well informed as
A liar is therefore obliged to feel like a gallow
, and a habitual liar very soon comes to look
. If there be no higher motive than one's own
t and welfare in speaking the truth and avoiding
